Among the most significant translation centers were the schools of the Muslim world at Baghdad, Seville, Toledo, and Cordova, where Greek philosophy and science were translated into Arabic. From the 10th to the early 12th centuries, these centers, in particular Toledo, played host to a number of Christian philosophers who translated Arab texts into Latin and brought back to the West Greek texts that had been lost. Another important center for this work was the Kingdom of the Two Sicilies, where scientific, diplomatic, and religious translators worked between Latin, Arab, and Greek. But even there can be found flashes of the ancient rhetorical theories of translation. Henricus Aristippus, Archdeacon of Catania (fl. 1100–1170), supported illuminist arguments for literal translation by quoting Horace's *Ars poetica* 361–362, which compared poetry to a picture that is different according to the angle from which you view it. Between the 9th and 16th centuries, there were Latin communities in Constantinople and Greek ones in the West that kept up a steady flow of translation between Latin and Greek in an effort to heal the breach between Eastern and Western Christianity.

The 13th-century controversy at the University of Paris over translating Greek philosophers from Arabic versions caused a fierce discussion of translation. Roger Bacon, arguing from lexical and terminological evidence, condemned it out of hand in his *Opus tertium*, while other philosophers, notably Thomas Aquinas, speculated on the nature of translation, seeing it almost as a barter transaction in which fair value must be paid. After attempts to condemn Aristotle as corrupt and corrupting, his works were retranslated from the Greek texts to rid them of Arab accretions. The greatest of these translators were William of Moerbeke (1215–1286), a Dominican friar, and Robert Grosseteste (1168–1253), Bishop of Lincoln.

Toward the Vernaculars

St Cyril and St Methodius (early 9th century) Christianized the Slavs and translated the Greek liturgy and Bible into Slavonic. In England the first Bible translation was the verse rendering of Caedmon (7th century). A century and a half later, Alfred the Great (848–899) ordered Pope Gregory the Great's *Pastoral care* and other important ecclesiastical documents to be translated into Anglo-Saxon to counteract a certain laxness in the English church. In Germany, the English missionary St Boniface (673–754) produced one of the early versions of the Scriptures. During the 8th century, there was much legal translation between the vernaculars and Latin as new codes were evolved from Roman Law.

After the Christian conquest of Spain, the kings, particularly Alfonso el Sabio, commissioned technical

translations from Arab and Latin into the vernacular. By the 14th century, there existed a full corpus of medical works in Spanish and Catalan. In France, Charles V founded a similar cultural center in his court. His translators included men of letters, administrators, and scientists. The most important was Nicole Oresme (1320–1382), reputed to be the first to translate Aristotle into a vernacular language. London, too, was an important center of royal patronage, and gained dramatically in importance after William Caxton (1422–1491), a skilled translator, set up his printing press.

Literary translation into vernacular languages, either from Latin or from other vernaculars, began around the 10th century. The first translations of classical rhetoric date from this period – vernacular writers saw such translation in the same light as Livius Andronicus had seen it 1200 years before: it was a way of bringing the language to maturity. For the general public, there were versions of Ovid and Virgil, very often taken from medieval Latin reworkings. Epic poetry, like the *Chanson de Roland*, was also translated widely, so most of this great medieval epic exists in a large number of dialects and languages. Much of the really important translation was in the hands of the troubadours, who translated very freely between the vernacular languages, often extempore and as part of a performance.

The laity benefited from translation of popular devotional books, much of it anonymous. Boethius's *Consolation of philosophy* was very popular, and was normally taken from a French version, for example, Chaucer's translation. Many countries produced versions of the epistles and gospels used at Mass, and it seems that these were often read while the celebrant read the Latin.

Whereas a technical translation remains very close to its original, literary translation is extremely free. The first attempts to apply linguistics to translation seem to be the orthodox attacks on the 14th-century Lollard Bibles: the claim was that translation from Latin to the vernaculars was impossible because of lack of formal identity between language resources. The Lollard reply turned on functional arguments – if one could do the same or similar things in English (i.e., construct sentences, show the line of argument) one did not need formal identity.

Renaissance and Humanism

Philosophy and Science

As the Turks were increasing the pressure on the Byzantine Empire in the 14th century, Greek scholars began moving west. Once established, they made their living by setting up schools. Major schools were set up at Florence and Venice, both powerful trading republics with ruling families interested in scholarship, by Manuel Chrysoloras (1355–1415) and Constantine Lascaris (fl. 1450–1490), who soon distinguished themselves as translators from Greek into Latin and put translation at the center of the educated person's skills. Among their pupils were Marsilio Ficino (1433–1499), who translated Plato into Latin, and Aeneas Silvius Piccolomini (1405–1464), later Pope Pius II. In these schools, translation reverted to the manner and principles of the classical rhetoricians and thus dethroned the translation model of Boethius. An early pupil of the Florentine schools, Leonardo Bruni Aretino (1369–1444), translated Aristotle into Latin (ca. 1420) and wrote a rather pugnacious preface on the necessity of translating works in a style consonant with their elegance.

Because the basic training of a scientist was classical and philological, noted translators like Thomas Linacre (1465–1524), Professor of Medicine at Oxford, and Janus Cornarius (1500–1588), first Dean of Medicine at Jena, scoured European libraries for Greek medical and scientific manuscripts, edited them, and translated them into Latin. By 1600 practically every important Greek work on science and philosophy had its humanist Latin version for use in the medical schools, and in many cases a vernacular version as well. Alongside these were translations from texts on alchemy, both works ascribed to the 13th-century scholastics like Roger Bacon and Albert the Great and books by later alchemists, like Basil Valentine and Nicholas of Cusa. Contemporary alchemists like P. A. Paracelsus (1493–1541), who wrote in their own languages (in the case of Paracelsus, German), were translated into Latin and from there into the local vernaculars. Gerhard Dorn (fl. 1570–1590) was the most prominent Latin translator of alchemy.

Religion

Sixteenth-century humanism was essentially religious, and translators were essential to Reformation and Counter-Reformation. They treated religious material no differently from other writings, assessing the worth of manuscripts, interpreting readings against parallel texts, etc. Translators first sought to produce Latin Bibles of humanist standard, and there were a large number of them. The most influential was the Greek–Latin New Testament (1523) of Desiderius Erasmus (ca. 1466–1536), the *textus receptus*, which studiously tried to be doctrinally neutral. But other Latin translators, like Théodore de Bèze (1519–1605) and Sebastian Castalio (1515–1563), produced

Bibles in fairly classical Latin, but with strong doctrinal leanings.

Of the vernacular Bibles, Luther's (1534) was preeminent. Other German versions were produced by reformers in Switzerland. Luther influenced the Dutch version of 1537, the Swedish of 1541, and the Danish of 1550. Other important Protestant Bibles were the 1641 Italian version by the Calvinist Giovanni Diodati (1576–1649), which he himself turned into French in 1644, and the French Bibles of Jacques Lefevre d'Etaples (1455–1537) and Pierre Olivétan (d. 1538), and de Bèze's 'Geneva Bible,' which came out in 1528, 1535, and 1556, respectively. In Spain the first complete version of Scripture was published in 1569 by Cassiodoro de Reina (1520–1594), a follower of Jean Calvin's, and in Italy the first complete Bible was by Antonio Brucioli (ca. 1495–1566) in 1532. In England there was a long progression from the Tyndale Bible of 1526–1530 to the Authorized Version of 1611, which is an excellent example of teamwork. The work was divided among six 'companies,' which included theologians as well as experts in classical languages.

Catholic countries tended to lag in Biblical translation. Spain continued the medieval custom of translating the epistles and gospels used at Mass. France often readapted Protestant or doubtful Bibles; for example, the Catholic Bible de Louvain (1550) was Lefevre d'Etaples's edition brought up to date. Likewise in Germany: Hieronymus Emser's version (1523) tried to 'correct' those parts of Luther's Bible already circulating. In 1548 Nicolaus van Winghe produced a Dutch Catholic Bible that remained standard until 1926. In England the Douay–Rheims version, translated from the Vulgate, appeared in 1588 as an emergency measure to counter Protestant accusations, partially justified, that the Catholics were afraid of the Bible. Most of the Protestant Bibles were taken from the original Hebrew and Greek, the only major exception being Miles Coverdale's (1535), taken from the Vulgate. Until Ronald Knox's Bible in 1949, Catholic Bibles were almost exclusively taken from the Vulgate.

Developing vernacular liturgies was essential to the Reformation. Partial translations of the Catholic liturgy already existed in the 'Primers.' In England the Book of Common Prayer (1549) rose out of English versions from the 'Primers' and translations from the Sarum Missal and Breviary. The translation committee was headed by Thomas Cranmer (1489–1566), Archbishop of Canterbury. For the next 200 years, the Book of Common Prayer was translated into other European languages to serve Anglicans living overseas and missionary congregations. Other Reformers who created similar works of liturgical adaptation mixed with translation were Martin Luther and Jean Calvin (1509–1556). As the Reformation spread, there were translations of Luther's liturgy into Scandinavian languages, which were adopted for the normal worship. Translators also entered with gusto into religious controversy. Luther's and Calvin's polemical works were translated into most European languages, and rebuttals, both Catholic and Protestant, were translated and circulated just as vigorously. Luther's works were translated into English by Richard Taverner (1505–1575), who was responsible for Taverner's Bible (1539); and Thomas Norton (1532–1584), a noted scourge of both Catholics and Lutherans, translated Calvin's *Les Institutions de la Religion Chrestienne*, which Calvin himself had translated into French from his own Latin version. There was also some translation of Jewish prayer books and synagogue liturgies into vernacular languages, but as yet no Biblical work.

Literary and Educational Translation

The rise of the vernaculars as standard languages slowly shifted the focus of translation toward literature. However, what could be termed a 'modern language' changed subtly. The standard languages of political and cultural centers – English, French, Spanish, and Italian – moved in to replace those like Catalan and Provençal, which were losing ground. In the recognized languages, literary translation brought to fruition what the Romans from the preclassical dramatists to Jerome had to teach. The Italians were in the forefront, one of the most important names being Petrarch (1304–1374). The humanist printing presses, like those of Aldus Manutius (1455–1515), himself a fine translator, and Frobenius in Antwerp, commissioned vernacular translations and sold them widely.

In the rest of Europe, literary translation arrived late in the 16th century, though there were some earlier pioneers like Gavin Douglas (1474–1522), Bishop of Dunkeld, whose Scots version of Virgil's *Aeneid* is particularly interesting. The major inspiration was classical, within an Italian cultural dominance, although Jean Baudoin (1564–1650), Lecteur to Marguerite of Navarre, translated a number of English books, including Sir Philip Sydney's *Arcadia*, into French. Poetry predominated, but by 1600 works of most of the common Latin and Greek prose writers had been translated into modern languages. In France, among the important translators were the group of poets centered around Pierre Ronsard (1524–1585), known as the *Pléiade*, whose interest lay in the latest from Italy as well as Greek and Latin literature; and Jacques Amyot (1513–1593), whose French version of Plutarch's *Lives* was translated into

English by Sir Thomas North (a. 1535–a. 1601). In England, Henry Howard, the Earl of Surrey (1517–1547), was known for his translations of Petrarch and the classics, and, the most famous of all, George Chapman (1559–1634), for his Homer. In Spain the Franciscan poet Fray Luis de Leon (1520–1591) was also renowned for his translations from classical literature.

Though the center of their intellectual world was in the classics, the humanists saw popular education as a priority. Educational works by Erasmus (particularly the *Colloquia*) and Luis Vivès were widely translated. One of the most characteristic manifestations of this interest was concern for the education of the 'Prince,' that idealized Renaissance figure who embodied all possible human virtues. The tone was set by works such as *Doctrinall of princes* (1533), translated by Sir Thomas Elyot (1490–1546) from the Greek of Isocrates, and the versions of Castiglione's *Il cortegiano* by Thomas Hoby (1424–1585; English), Juan Boscan (d. 1542; Spanish), and Bartholomew Clerke (1537–1590; Latin). Machiavelli's work was translated but feared, and the English version of *Il principe* by Sir Thomas Bedingfield (d. 1613) was unfavorably noticed by Queen Elizabeth I and remained in manuscript until after 1960.

The Age of Reason

Literary Translation

During the 17th and 18th centuries, literary translation was dominated by French models, the notorious *belles infidèles*, which judged a translation according to contemporary norms of taste. In France the salon, in Britain the coffeehouse, and everywhere in Europe the learned society were essential to the development of translation at this time. The influence of the Royal Society and the Académie Française were seconded by periodicals like the *Gentleman's Magazine* and *L'année littéraire*. In France the dominant figure was Nicholas Perrot d'Ablancourt (1600–1643), whose ruling principle was to "remove everything that could wound our sensibilities." The same principle was followed by Anne Dacier (1651–1720) in her Homer, which is a classic of the style. The dominant figure in Britain was John Dryden, who took his famous typology of 'metaphrase,' 'paraphrase,' and 'imitation' from French practice. He opted for paraphrase as ideal, but in practice his poetic translation leaned more toward 'imitation.' German translators, like Bodmer (1698–1783), Breitinger (1701–1776), and Gottsched (1700–1776), followed the same line.

Though classical works were still the staple of the literary translator, there was also work from modern languages, much of it for recreational reading. This work included Latin version of contemporary poets, the version of *Paradise lost* by William Hogg adding to John Milton's international reputation. From the end of the 17th century, translators begin to demand authenticity and close translation. T. R. Steiner traced this change to the influence of Pierre-Daniel Huet (1630–1721), who championed literal translation. Among English translators affected by him were Sir Edward Sherburne (1616–1702). The new manner became standard later in the 18th century, as in the translations ascribed to Tobias Smollett (1721–1771) in England and taught in France by Charles Batteux (1713–1780), a noted translator from Latin and Greek; in Spain, in Antonio Capmany Suris y Montpalau (1742–1813), who translated from French; and in Russia, in Vasily Trediskovsky (1703–1779), who worked from classical languages. The 18th century was discussed at length in Tytler's 1791 *Essay on translation*. But the old manner persisted – L'Abbé Prévost, one of the few who kept away from classical translation and specialized in translation from English, published a version of Richardson's *Clarissa Harlowe* that followed *les belles infidèles* to the point of wounding the author. And Jacques Delille (1783–1813) was still translating like this during the French Revolution.

Religious Translation

The Dutch Protestants produced their standard Statenbijbel in 1637. Luther's German Bible was kept constantly up to date, and the Douay–Rheims Bible was updated by Bishop Richard Challoner (1691–1781) in 1763. Martini, the Bishop of Florence, translated the Bible into Italian between 1769 and 1781, and the official Spanish version of 1793 was also from the Vulgate. If attempts like the Bible of Lemaistre de Saci (1613–1684), taken from the Vulgate, are set aside, in France translation was merely an incidental part of Biblical scholarship. This gathered pace during the 18th century with the work of Richard Simon (1638–1712), the author of a huge Biblical encyclopedia, and Charles Houbigant (1686–1783), whose Latin version of the Hebrew Old Testament has an important preface on translation. This work came into its own in Britain at the end of the 18th century among those who were trying to replace the Authorized Version. The greatest translator of the period was George Campbell (1719–1796), principal of Marischal College in Aberdeen; his Four Gospels (1789) was meant to be an ecumenical version. At the beginning of the 19th century, it was frequently published with the epistles by James MacKnight (1721–1800) and the books of Acts and Revelation by Philip Doddridge (1739–1786). Campbell's

work is notable for its voluminous notes and introduction, which was a summing up of 18th-century thought on translation in general.

Strangely enough, French Catholicism provided Protestant Europe with much devotional literature, Fénélon, the Archbishop of Cambrai, being a popular author. As Catholicism became more sure of itself, there was a great deal of translation into vernaculars of traditional devotional literature, like *The imitation of Christ*, ascribed to Thomas à Kempis (ca. 1379–1471) – even in England after the break with Rome. There was a fair amount of polemical translation as well, the most virulent occasioned by the 1643 quarrel between Port-Royal (*see* **Port-Royal Tradition of Grammar**) and the Jesuits, and centering around Pascal's *Lettres provinciales*, though the fallout from the Reformation kept translators going for the whole century. Translators tried to temper the acrimony by translating works on religious tolerance, like the religious writings of the great Dutch jurist Hugo Grotius.

Technical Translation

At the beginning of the 17th century, three scientific paradigms were fighting for supremacy, and for the warring scientists translation was a professional responsibility. First there was the scientific paradigm, of which Thomas Linacre, the founder of the Royal College of Physicians, was typical; the second was the alchemist paradigm; and the third was the new philosophy of science taught by Francis Bacon and René Descartes. There was still a little translation from classical writers, but the humanist versions remained standard.

Not only were the latest medical sources translated, but also the works of medievals with a reputation, like Albertus Magnus, Roger Bacon, and Ramon Lull. Alchemists and surgeons often wrote in their own languages. The most famous of these authors, Paracelsus and Glauber, were still translated into Latin for international consumption. In Britain in particular, both vernacular and Latin translation had its political side, as is quite clear from noted Puritan apothecaries like Nicholas Culpeper (1616–1654) and from Royalist translators like Elias Ashmole (1617–1692). The fight continued all over Europe until about 1680.

Between 1660 and 1700, there was a staggering amount of translation of the writings of Bacon, Descartes, and, at the end of the century, Isaac Newton. This was a time when scientists were beginning to write in their native languages, with consequent difficulties for readers in other countries. Robert Boyle and Isaac Newton commissioned their own Latin translations, and sat on the translators' shoulders. Descartes was well served by his French translator, le Duc de Luynes, and badly by the Dutch mathematician Frans van Schooten (1615–1660). In the rare cases where scientists were incapable of writing Latin (e.g., A. van Leeuwenhoek), they found anonymous Latin translators. Scientific translation was largely in the hands of the medical profession, encouraged by publication subsidies. The demand was so high that entrepreneurs made use of unemployed university graduates as translators, usually without acknowledging their help. The peak of this activity was in the period 1700–1745 and coincided with the general acceptance of the scientific ideas of Descartes and Newton. Indeed, it is doubtful that Linnaeus, the famous biologist, Albrecht von Haller, the founder of physiology, or T. O. Bergman, the noted Swedish chemist, would have had the effect they did if they had not written in Latin and been translated into the vernaculars.

By the early 18th century, vernacular work on medicine was usually translated directly into modern languages. By the late 18th century, the center of scientific translation in Britain was moving north to the scientific communities of the Midlands and Scotland, who were in contact with France, Germany, and Sweden. In France the center was still Paris, where Louis-Bernard Guyton de Morveau (1737–1816) was particularly active in both translation and research. Creative physicians like William Lewis (1714–1781) of Edinburgh, de Rusieux of Paris, and J. H. Ziegler of Germany were translators and were translated.

The 17th century had produced a lot of 'gentlemanly' translation, on gardening, building, and architecture, much of it from French and Italian sources; for example, the translations by John Evelyn (1620–1706), on gardening and art, and translations of important Italian architects like Giacomo da Vignola and Andrea Palladio. The 18th century, too, was also marked by the translation of applied science, much of it from French, Swedish, and German. A good part of it dealt with agriculture – the concentration of population in the new towns demanded intensive agriculture if the people were to be fed. There was also much on the manufacture and use of weapons, the French being in the forefront. Navigation and traditional crafts like dyeing also benefited from translators. However, the most radical changes came in pharmacy, which followed the 'new chemistry' so closely that its practice was reformed.

Education was an important issue, and authors translated into most European languages, including Latin, ranged from Jan Amos Comenius to John Locke. Much translation of history, education, and the like was commissioned for political purposes. In Britain, Cromwell's Parliament commissioned legal

and historical translation in an effort to legitimize the regime. On his return to power (1660), Charles II used translators like Dryden to translate political, if not polemical, works in support of the Royalist cause. In the following century, Adam Smith's *The wealth of nations* was translated into Spanish for the financial guidance of the government (1794), and in France there were at least four translations of Smith's work between 1793 and 1815, each coinciding with a change of regime, T. R. Malthus's work on population was also translated. As usual, a good deal of this translation was anonymous, and done to meet specific scientific needs.

The 19th Century

Romanticism and Literature

It was not until the rise of Romanticism that 'translation' became popularly identified with literary translation. The precursor of the movement, Johann Gottfried von Herder (1744–1803), left to it a thoroughgoing Platonism that saw man and his society as creatures of the language spoken. For Herder, translators were the 'morning star' of a literature, because they introduced a literature to the great things in other literatures. His own contribution to German was a collection of translations from European poetry, the *Volkslieder* (1778–1779), which imitated the original meters as the appropriate dress for the verse. Classical meters were acclimatized in German by Friedrich Klopstock (1724–1803); English experimentations, even by the poet Tennyson, were never successful.

Herder's view of translation as a hermeneutics of text was refined by Friedrich Daniel Ernst Schleiermacher (1768–1834). Romantic translators took on two interlinked tasks: the first was penetration to 'pure speech,' supposed by Friedrich Hölderlin (1770–1843) to underlie all languages; the second was to present author and text unadorned to the reading public in the second language. Hence, the famous classification by Johann Wolfgang von Goethe (1748–1832): literal, 'parody,' and interlinearversion. The first was word for word, and to be used if no other was possible; in 'parody' translation, the translator imposed himself and his society on the original; and the interlinearversion was the penetration to the very essence of the original.

All of these theorists were practical translators as well, Hölderlin and Schleiermacher translating from Greek poetry, and Goethe and Wilhelm von Humboldt from both modern and ancient languages. In France, Goethe's ideas were taken up by Madame de Stael, whose *Esprit des traductions* (1816) is one of the seminal statements of Romantic ideology. Such ideas were also illustrated by the version of *Paradise lost* (1836) by René de Chateaubriand, who boasted that he had kept both the virtues and faults of the original. On a more pedestrian level, Amadée Pichot (1795–1877) publicized English literature with assiduous but extremely literal translations of contemporary writers. In Britain, after a much-reviled translation of *The sorrows of young Werther* from a French version, Goethe's most prominent publicist was Thomas Carlyle (1795–1881); in America, Bayard Taylor (1825–1878); and in Italy, Michele Leone di Parma (1776–1858). But Goethe's ideas had special impact in Russia and other parts of Eastern Europe, where translation still had the creative status it had enjoyed in the Western Renaissance. Romantic poets, English, German, and French, were translated by Zhukovsky (1783–1852). Dickens was a favorite subject: both his French translator, Pichot, and his Russian, Vvedensky (1813–1855), wrote to him. Shakespeare was another favorite, the German Tieck-Schlegel version being almost a national monument, unmatched by any other version. Romanticism also occasioned the midcentury vogue of Eastern literature. Eastern languages were taken up in France by Emile-Louis Burnouf (1821–1907), and in Germany by the Romantics, in particular von Humboldt. The most famous English translation of Eastern poetry is probably *The Rubaiyat of Omar Khayyam*, (1859) from the Persian by Edward Fitzgerald (1809–1883).

The crux of the Romantic legacy was the nature of authenticity. It was given public airing in the famous quarrel between Matthew Arnold (1822–1888) and F. W. Newman (1805–1897) over translating Homer. Newman believed that the archaic and antique in Homer should be presented to the reader of English by conscious archaism, while Arnold insisted on presenting Homer as poetry that conformed to the contemporary experience of poetry. Probably the greatest of Newman's partisans were John Conington (1825–1869), Professor of Latin at Oxford, and Sir Richard Jebb (1841–1905) of Cambridge. Robert Browning's *Agamemnon* (1877) is an excellent example of the Newman style, and his preface recalls that of Chateaubriand to Milton's *Paradise lost*. Arnold's approach culminated in the translations of Dante and his circle by Dante Gabriel Rossetti (1828–1882). His cardinal principle was that 'a good poem should not be turned into a bad.' In other countries, particularly France, translation showed much influence of contemporary literary movements. Charles Baudelaire (1821–1867) changed Poe from a very good second-rate American writer into a first-class French one, and Leconte de Lisle (1818–1894), a true Parnassian, went back to the classics. In Germany the development of literary translation followed much the

same lines as in England, with conflict between the antiquarian and the authentic in the Romantic sensibility.

Romantic ideas on translation also had their political side. The subject peoples of the Austro–Hungarian Empire, particularly in what became Czechoslovakia, were strongly influenced by the nationalism inherent in Romanticism and plotted revolution. Elsewhere, for example, in Canada, where English and French were in close contact, Romantic ideas on the teaching role of the translator affected the problems of preserving the identity of the minority and interpreting the two cultural groups to each other, and the French minority had to decide whether to absorb material from the dominant culture or to stand aloof. The Canadian situation is interesting for the critical role played by newspapers in fostering translation between the two languages, especially by serializing translated novels.

There was also some translation of libretti; this practice continued into the 20th century. Gilbert and Sullivan operas were presented in German in Germany, and French and Viennese operettas (e.g., the Strauss family and Offenbach) in London in English. There was also some translation of French, Italian, and German operas into other European languages, though nowhere near the 20th-century scale of such translation. German *lieder* and the French art songs were also translated, often very badly, for the drawing room soprano and tenor.

Religious Translation

The issue of updating the Bible did not go away. In 1836 a Catholic historian, Dr. John Lingard (1771–1851), published a Bible with the New Testament translated from the Greek. Among Protestant efforts was the modernized King James Bible (1833) produced by the American lexicographer Noah Webster. During the 1850s pressure began to mount in England for a revision of the Authorized Version, if not a completely new translation, for Biblical scholarship had advanced considerably. In 1870 the Convocation of the Anglican Province of Canterbury set up a committee to revise the Authorized Version. Other Protestant churches joined in. In 1881 the English New Testament was published, and in 1885 the whole Bible (the Revised Version). The American Bible Union (ABU) had been established in 1864 and sent observers to keep an eye on what the English Anglicans were doing. The American Standard Version was published in 1901.

Spain was still nervous of Bible translation; however, the British and Foreign Bible Society was happily supplying Protestant versions of the Bible in European languages – for example, a revision of Valera's 1625 Spanish version was reprinted many times between 1806 and 1817, and a Catalan New Testament was produced by J. M. Prat (1832). At the end of the 19th century, l'Abbé Augustin Crampon (1826–1894) produced what was to become the standard French Catholic Bible of the early 20th century. For French Protestants, the most important Bible was the version of Louis Ségond (1810–1885), whose Old Testament came out in 1874; the New Testament followed in 1880.

The Jews were once again facing the ancient problem: a religiously vital social group that could read but not understand the sacred books. In America, Rabbi Isaac Leeser (1806–1868) published his English version of the Old Testament in the Masoretic text in 1853. The Jewish Publication Society, founded in 1892, produced an official Jewish version in English in 1901. Other Jewish communities followed suit.

The Oxford Movement in the Anglican Church sought to prove its essential Catholicism by returning as far as possible to early Christian practices. There was much interest in the Fathers of the Church, in both doctrine and hymnody. The movement's search for ancient Christian hymns began with the Roman Breviary, then passed to the Paris Breviary, and finally to pre-Reformation rites like the Sarum (from Salisbury) and the York. The leading translator was John Mason Neale (1818–1866), whose hymn versions took into account the traditional melodies of medieval Service books. Most of his work appeared in *Hymns ancient and modern* (1861), edited by Reverend Sir H. W. Baker (1821–1877). Another important contributor to this famous hymnbook was Catherine Winkworth (1827–1878), an early feminist, whose speciality was translation from German, and particularly the Lutheran hymns.

Technical Translation

Technical translation in the 19th century did not benefit at all from the Romantic revolution; indeed, its practice had continued in the same manner since the early 17th century. The work of Michael Faraday, J. J. Berzelius, the Swedish chemist, and other scientific pioneers was widely translated. The quantity of translations increased as the century went on, though now the scientist was no longer his own translator. In the humanities, by contrast, the task of translation was still regarded as the professional responsibility of contemporary philosophers and social scientists.

Less is known of the translation that went on in the bureaucracies of the Ottoman, Austro–Hungarian, or Russian empires than of the work carried out in the empires outside Europe. European colonial expansion gathered pace during the 19th

century. Training local people as interpreters was the first step; colonists then learned the native languages. Soon colonial administrators benefited from a loosely organized translation profession. In most places a system of professional certification slowly developed. For example, in the previous century Sir William Jones (1746–1794), though most famous for demonstrating that Sanskrit was an Indo–European language, was an assiduous translator from Eastern languages, specializing in law. His ideas had considerable influence on later British colonial policy.

Tensions between French and English, and English and Spanish, antedated British expansion in North America. The resulting warfare occasioned a fair amount of translation. Bilingual officers worked as volunteer translators between English and French or Spanish. Apart from this, there is very little on record of anything beyond *ad hoc* translation before the British takeover of Canada in 1759, the Louisiana Purchase of 1803, and American expansion into the Spanish territories that now make up parts of Florida, Texas, and California. The press played a very important role. It was to it that the various Canadian governments (and also the government of Louisiana) later turned when they needed translators.

Missionary Translation

During the 18th century, European expansion into the New World revived ancient problems entailed in translating between sophisticated and unsophisticated languages. Little is known of how early Christian missionaries, like St Boniface (d. 755), had faced the problems of creating literacy before being able to translate the Bible into languages previously unwritten. Until the 16th century it was trade, not colonization, that usually went with the missionary. A new pattern developed in the Americas, where in the British, French, Spanish, and Portuguese dominions, missionary and colonist often arrived together, and at times cooperated. The practice of the New England and the Jesuit missionaries with Amerindian languages was typical: translation of the Bible and the introduction of Christian worship – for example, by Thomas Mayhew (d. 1657) and John Eliot (d. 1690) – were preceded by and prepared for the production of grammars and lexicons; literacy as well as conversion was an objective.

Missionary translation was first given direction by the formation of the Congregatio pro Propaganda Fide in Rome in 1662. There are reports of translations of the Bible into Eastern languages mainly from Catholics like St Francis Xavier (1506–1552), and the Congregation has continued active translation. On the Protestant side, the Society for the Propagation of Christian Knowledge (1698), the Society for the Propagation of the Gospel in Foreign Parts (1701), and the Moravian Brotherhood (founded 1722) took a vital part in Bible translation into non-Indo–European languages. Perhaps the most important development was the foundation of the interdenominational British and Foreign Bible Society in 1804, which had as its sole aim the production and distribution of vernacular scriptures all over the world, including England and Wales. Early in the 19th century, the Church Missionary Society of the Anglican Church entered into an agreement about cooperation. Parallel Bible societies were founded in Scotland and the United States. In many parts of the world, Catholic and Protestant Bibles were in competition. There are extensive records of Protestant liturgical translation into the languages of the mission fields: the Tamil translation of the Lutheran liturgy published in Ceylon in 1781 is far from unusual. Indeed, Anglican translation of the *Book of Common Prayer* into the languages of the Indian subcontinent helped lay the foundations for the development of eastern forms of Christianity. During the 19th century, most of the vernacular Scriptures published by these bodies were translated in the field, often with the help of native speakers.

In the United States in particular, linguists began to take a large hand in Bible translation in the mid-20th century. After World War II, American Bible Societies merged into the United Bible Societies (UBS), with its own periodical, *The Bible translator.* On the evangelical side, the work of UBS was grouped around the Summer Institute of Linguistics, also known as the 'Wycliffe Bible Translators.' One of its leaders was Eugene Nida, whose work on the theory of translation focused specifically on the Bible. The linguistics of the mid-20th century, with its strong anthropological bias, suited this work.

The Qu'rān was also translated early into European languages. There is a 'curiosity-oriented' translation into Latin, dating from the 12th century, ascribed to Robertus Ketenensis and Hermannus Dalmata. This was republished in 1543 by Theodore Bibliander (1504–1564). There are also a few 16th-century Latin versions of the Qu'rān for the information of Christian missionaries. It was a popular book among European translators during the 19th century, versions having been made in all the important European languages. Because Muslims have the same attitude to the Word of God as Jews, translation of the Qu'rān for religious purposes is suspect. Nevertheless, a number of modern translations into European languages have been tolerated by the authorities for use by European Muslims. The Western interest in Eastern

religions has also occasioned much translation and commentary on the Hindu scriptures.

The 20th Century

Religious Translation

Christian The dominant motivation was the increasingly urgent need to replace the great European language translations of the past by up-to-date versions. This coincided with two contradictory movements – the centripetal force of ecumenism, which increased pressures toward a Bible common to all Christian churches, and the centrifugal forces created by new types of Christian and Jewish fundamentalism. In English there are a huge number of Bibles, the best known early 20th-century ones being The New Testament: A New Translation by James Moffat in 1913, with the Old Testament following in 1924, and The New Testament: An American Translation by Edgar J. Goodspeed (1923). In 1913 a version of the Old Testament by Powis Smith and others was published with Goodspeed's, the whole being known as The Bible: an American translation.

Among 'official versions' in English, the most notable Protestant versions are the American Revized Standard Version (1952) from the International Council for Religious Education, and the British New English Bible (1961), which was initiated by the Church of Scotland but which eventually became a joint effort by most of the mainstream Protestant denominations. Later on, a printing of the New English Bible was authorized by the Catholic Church. The Catholic church first published the Westminster Bible (1913); Monsignor Ronald Knox's version was published in its entirety in 1949 but was superseded by the Jerusalem Bible in 1966. The Knox is the last important version from the Vulgate, and it was done with a close eye on the Greek and the Hebrew texts.

Other important modern Bibles are the Spanish versions by Nalcar-Colunga (1944) and Bover-Cantera (1957). The Catalan version, from the Benedictine Monastery at Montserrat, began publication in 1926, but the work was suspended between 1936 and 1950 by the anti-Catalan policies of the Franco government.

The Roman Catholic and various Orthodox churches produced bilingual service books. Liturgical reforms instituted by Pope Pius X (1903–1914) encouraged the production of a very large number of missals of various states of completeness for the laity. There were also a few translations of the Divine Office for the laity and certain religious communities. One of the most interesting of these is *Byzantine daily worship* (1969), translated from the Greek *Horologion* (Breviary), and the ancient liturgy of St John Chrysostom for the Greek Uniate community worldwide. The Anglican Church continued translating the Book of Common Prayer into the languages of the British Empire and Commonwealth. After Vatican II (1962–1965), national commissions were set up throughout the Catholic world to organize the translation of the entire Roman Catholic liturgy into the vernaculars. For international languages like English, French, and German, there were international commissions that came to agreement on language standards and other matters. In the name of ecumenism, the various churches cooperated in versions of common texts like the Creeds and the Gloria in excelsis Deo.

Jewish The most notable Jewish Bible translators, mainly because of their very telling and coherent arguments for literal translation, were the philosopher–theologian Martin Buber (1878–1965) and Franz Rosenzweig (1886–1929), whose German Bible, with a preface, was published 1926–1938. Their principles were taken up by Henri Meschonnic (1932) in France, and applied to secular translation as well. Jewish bilingual versions of the synagogue liturgies and private prayers go back a considerable time, at least to the 16th century. However, as Reform Jews began to worship in the local vernaculars, unilingual service books were produced from the middle of the 20th century onward. Among the Jewish Bibles in English, The Holy Scriptures by the Jewish Publication Society was published in 1917.

Probably the best of the modern versions is the French Bible de Jérusalem (1948–1954) from the Ecole biblique de Jérusalem. The English Jerusalem Bible (1966) came from the same team, and they also produced a Spanish translation (1987).

Technical Translation

The 20th century saw the rise of the translating profession, centered on technical work. The trigger seems to have been the founding of the League of Nations in 1918. By that time, many governments had translation offices for administrative purposes. After World War II, these expanded quickly, following the postwar political and trade patterns. Private firms began to follow the lead of governments and created their own translation sections to translate everything from technical reports and instruction manuals to publicity. It was only a matter of time before freelance translators began organizing themselves as commercial operations and into societies like FIT (la Fédération Internationale des Traducteurs). Specialized training

is a 20th-century phenomenon, and it gained pace in the 1960s with courses being established in universities and specialized schools. There continued to be a lot of in-house translator training, one of the finest translation schools in the world being run by the electronics firm Philips, in the Netherlands.

There has been a growing body of theory of technical translation, with some attempt to relate it to the mainstream literary and religious work. One obvious result has been the creation of specialities like terminologist and documentalist. The great expansion of translation in the first half of the 20th century occasioned experimentation in machine translation (MT), which stemmed from a memo from an American founder of the field, Warren Weaver, in 1947 on applying code-breaking techniques to languages. Results have proved limited. Its most useful spinoff has been the development of automated dictionaries.

Literary Translation

At the beginning of the 20th century, literary translation remained what it had traditionally been, a searching apprenticeship for the creative writer. Nineteenth-century manners of translation spilled over into the first half of the 20th with the vaguely Swinburnesque manner of the translations from Greek by Gilbert Murray (1866–1957), and the versions of modern and classical literature from Valéry Larbaud (1881–1957), Paul Valéry (1871–1945), André Gide (1928–1945), and the English version of Proust by Scott Moncrieff. In Germany figures like Ulrich von Wilamovitz-Moellendorf (1848–1931) carried the Romantic tradition to its limits. Reaction against the tradition started at the beginning of the century, with Rudolf Borchardt (1877–1945), and continued in Symbolists like Walter Benjamin (1892–1940). In Slavic Europe, translation has remained an activity central to the work of creative writers without excluding specialist translators of literature.

The decisive break in the tradition came with Symbolist writers and writers under Symbolist influence like Ezra Pound (1888–1972), Yves Bonnefoy (b. 1923), the Russian Balmont (1867–1943), and the German Walter Benjamin, who developed the Romantic idea of the language shape having its own meaning. Attitudes and practice range from Benjamin's attempts to get rid of meaning altogether to Pound and Henri Meschonnic, who successfully walked the tightrope between sound and sense, with some striking results. Bonnefoy, in particular, came very close to some of the 20th-century theorizing on the linguistic element in translation in his Shakespeare translations.

Under the pressure of changes in education, translation from classical languages diversified; beside translations for the reader's recreation grew up translations to help students – for example, in English-speaking countries the Loeb editions from Harvard University Press, and in French the Editions Budé. Translation began to acquire its own impressarios. One of the most important was Betty Radice (1912–1985), a classical scholar and excellent translator in her own right, who was editor of the Penguin Classics series.

It is in the translation of modern languages that there has been the most change. Theater has taken the interest of many translators, even if at times they chafe against what producers do to their texts. Translation of libretti has continued, some of it anonymous, and opera has attracted people of the caliber of W. H. Auden (1907–1973). As had happened during the Middle Ages, hitherto unimportant languages and literatures have gained worldwide recognition through translation. Eastern European work has become influential, and smaller European countries important, as they appreciate that translation provides access to a greater audience for their literatures. Indeed, at times translation into the languages of non-Communist Europe was the only way in which dissident writers like Milan Kundera in Czechoslovakia and Alexander Solzhenitsyn in the former Soviet Union could be published at all. As well, former European colonies developed their own distinctive literary voices; they attracted the notice of translators and produced translators themselves – for example, Octavio Paz from Mexico. The number of translators from the former European colonies in Africa and Asia has been growing. Many bilingual countries have attempted to foster literary translation for the sake of national cohesion. Canada, for instance, subsidizes translation of Canadian French writers into English and vice versa. At times, translation has been used as it was in 19th-century Europe, as a nationalist rallying point, in Quebec, Scotland, and Wales.

Interest has grown in hitherto unconsidered literatures. Many classical translators – for instance, Peter Green – have taken up translation of modern Greek literature. There has also been increased interest in Eastern literatures by translators like I. A. Richards and Achilles Fang. The 20th-century literary prizes have had an important influence on the extent of translation: Nobel Prize winners like Patrick White, the Australian, and Alexander Solzhenitsyn, himself a fine translator, have been translated worldwide.

New areas of translation have developed, including popular fiction for the mass market (e.g., the works of detective writers Georges Simenon and Agatha Christie) and film dubbing, which reconciles the

sense of what is said with the observable features of lip and face movement.

Theories of translation have followed changes in linguistic and literary theory. Symbolist theories of literature have been most prominent in the translation theories of people like Ezra Pound and Yves Bonnefoy. In Eastern Europe, translation theory has been of vital interest – for example, the Prague School, whose linguistic theories did not prevent them from producing extremely perceptive work on poetics and translation. Linguistic theories of translation have been a feature of the 20th century, though usually in complete isolation from the more traditional literary stream. In the English-speaking world, American structuralism gave rise to the theories and practice of the Summer Institute of Linguistics, typified by the work of Eugene Nida; and English translation theory has risen out of the work of J. R. Firth and M. A. K. Halliday. In the French-speaking world, a contrastive linguistics applied to translation was developed from the Geneva School, chiefly from the theories of Charles Bally. Its first manifestation was the stylistique *comparée* of Malblanc, and Vinay and Darbelnet; it was further developed by reference to the theories of Gustave Guillaume and Culioli's theories on enunciation. Like the linguistics of Prague, contrastive linguistics takes account of discourse phenomena. The end of the 1980s saw some attempt to combine both linguistic and literary theories of translation by absorbing the idea of linguistic transfer into a concept of translation as a communicative act whose source and target texts are embedded in differing cultural matrices.

Translation: Pedagogy

M Davies, University of Vic, Vic, Spain
D Kiraly, University of Mainz, Mainz, Germany

Introduction: From Pedagogical Translation to Translation Pedagogy

Two rather different educational settings are likely to come to mind if we think of translation pedagogy. In foreign language classes in many parts of the world, pedagogical translation into the mother tongue has traditionally been used to practice and demonstrate comprehension of foreign language structures and lexical items, whereas inverse translation activities, in which students produce texts in a foreign language on the basis of a native-language original, are geared toward having learners practice and demonstrate their ability to actively use those structures in linguistic production. Translation as a pedagogical tool has moved in and out of fashion as a teaching and testing technique in foreign language classrooms for many decades, and the debate for and against this practice still rages today.

There is an essential difference between this type of pedagogical translation, however, and the variety in which professional translators are engaged. In the former, there is no real linguistic gap to be bridged, no target reader who needs the translated text in order to comprehend a message in a language she or he does not understand; there is no client and there is no real communicative situation. This kind of translational activity might perhaps best be seen as a type of transcoding, where the translator essentially manipulates contrasting structures in two languages.

The consensus view in translation studies today is that professional translation, on the other hand, is a complex cognitive, social, and often technical process of interlingual and intercultural communication. In this article, the approaches, strategies and techniques for helping future nonliterary translators to acquire the necessary professional language mediation skills to accomplish such communicative tasks for professional purposes comprise translation pedagogy.

The Setting for Learning: Translator Education Programs

Although on-the-job learning and lifelong learning are key features of a translator's education today, translators of pragmatic (e.g., nonliterary) texts around the world often receive their initial training in university-level programs (both undergraduate and graduate). Pym and Caminade (1995) estimated that there were close to 300 such programs, and the number is still rising. In Europe, most of the first university programs for the training of translators were established in German-speaking countries. The University of Heidelberg set up the very first one in 1930. This was followed by programs in Geneva (1941), Vienna (1943), Graz (1946), and Innsbrück (1946) – all of them notably subsumed within philology departments (Snell-Hornby, 1998: 31). The interpreting school in Germersheim (later to become the interpreting and translation faculty of the University of Mainz) was founded by the French occupational forces in 1947, and the Saarbrücken program was started in 1948. Similar institutions were founded throughout Western Europe within a short period, including schools in Antwerp, Brussels, Mons, Copenhagen, Aarhus, and Triest. Then in 1957, the Ecole Supérieure d'Interprètes et de Traducteurs (ESIT) and the Institut Supérieur d'Interprétation et de Traduction (ISIT) were established in Paris.

Following a series of meetings between representatives of the translator training schools in Geneva, Heidelberg, Paris, Germersheim, Saarbrücken, and Triest, the *Conférence Internationale Permanente d'Instituts Universitaires de Traducteurs et d'Interprètes* (CIUTI) was founded. In 1995, this international association of translator education institutions had 21 members. CIUTI both acknowledges the status of its members and contributes to their standing and prestige in the translation world. And yet, as Snell-Hornby points out, it is particularly the older institutions (which were formed as appendages to philology departments) that still suffer from their second-class status, essentially as language schools where translation competence was long equated essentially with foreign language competence (Snell-Hornby, 1998: 32).

This brings us back to translation pedagogy: when translation is understood essentially as a type of foreign language competence, it is hard to justify the need for a special pedagogy of translation. Hence, there have to date been few concerted attempts to develop systematic approaches to translation pedagogy. This is reflected in the fact that, despite the existence of nearly 300 translator education institutions around the world, there are still no degree programs for the training of translator educators. Attempts by CIUTI to develop translation pedagogy in conjunction with other international institutions have yet to bear fruit. Without suitable institutional settings for the systematic development of pedagogical approaches, strategies, and techniques, paradigms for translation pedagogy have been slow to emerge.

There are signs, however, that an awareness of the extreme importance of language mediation in today's global village is helping to bring about change for the better in this regard. The popularity of the summer courses in translation teaching at the Monterey Institute of International Studies, the Universities of Tarragona and Rennes (Gabr, 2001), and most recently the University of Vic reflects the interest on the part of practicing and prospective translation teachers in learning about and contributing to the advancement of translation pedagogy.

Partly as a result of the long-standing dependency of the major translator education programs on philology departments, the focus of attention in the early translator training programs was initially placed on translation competence – the ability to produce a text in one language on the basis of a text written in another language, with literary and cultural studies playing a separate and superordinate role in the educational process. Over the past decade or more, a shift has been gathering momentum in the direction of developing translator competence – that is, the superset of skills that translators can be expected to need in professional life today, including: linguistic but also interpersonal, (inter)cultural, technical, subject-matter, entrepreneurial, and research subcompetences.

The Emergence of Translation Pedagogy – Toward the Development of Translator Competence

Until translation studies began to take an interest in translation as a communicative process, there was essentially no difference between the pedagogical translation activities known to foreign language learners the world over and translation pedagogy as applied in the classroom for the training of professional translators. Aptly described back in 1977 by Ladmiral as a *"performance magistrale"* (instructional performance), the standard procedure was to have students translate a text at home, bring their faulty versions to class, and have them dissected by the teacher sentence by sentence, with different students offering sentences taken from their respective translations for review.

From this very limited pedagogical basis, translation pedagogy as a subfield of translation studies has begun to evolve over the past decade into a varied and complex subfield of translation studies. There are three major reasons for this trend: (1) advances in translation theory, (2) the application of findings from educational research to the teaching of professional translation skills, and (3) the advent of the personal computer and related technologies as essential tools for professional translators.

Advances in Translation Theory

For some of the most influential translation theorists in the 20th century (such as Georges Mounin; Wolfram Wilss, at least in his earlier works; and John Catford), translation was essentially a type of linguistic process based on principles of contrastive linguistics for two languages. As translation theory evolved, however, the consensus view expanded to include cultural, interpretive, interpersonal, cognitive, and even technical factors as well. With the advent of the functionalist approach in translation theory, with major proponents such as Katharina Reiss, Hans Vermeer, Christiane Nord, Hans Hönig, and Paul Kussmaul, the function or purpose of translated texts as communicative tools moved into the center of attention, where it remains today.

Although this article lacks space to even outline the great variety of factors that have been investigated to date, it is fair to say that translation studies as a field has moved radically in the direction of embracing an integrative approach to translation that sees itself as a multidiscipline with virtually no aspect of the communicative process being outside its scope of reference. Perhaps one of the most overriding shifts in translation theory has been from the static to the dynamic: from seeing the translation process as one of establishing equivalence between original and translated texts to seeing it instead as one of cognitive, social, and communicative action. Results of think-aloud studies on the mental processes involved in translation, focusing primarily on the interplay between intuitions and strategies, suggest that mental process research can be a fruitful source of knowledge about how experts and novices translate differently. Such research may well make valuable contributions to translation pedagogy in the future, for example in specifying a role for strategy and creativity training.

In any event, against the backdrop of the modern understanding of translation, translation pedagogy can no longer be reduced to a simplistic *performance magistrale,* where a teacher can be expected to transmit the knowledge necessary to achieve linguistic equivalence. As in all other domains of human activity, the skills and knowledge needed to act need to be developed through the authentic practice of that professional domain. Partly as a result of the equivalence-to-action shift in translation theory, there is an ever-increasing awareness that translation students must be actively engaged in the development of individually adapted skills for dealing with the

myriad unforeseeable combinations of factors that they will face in their professional work.

The Application of Findings from Educational Research to the Teaching of Translation

Dramatic changes are beginning to take place in the domain of translation pedagogy as the result of educational research in general and foreign language education research in particular. Although the philological orientation of the early translator education programs may well have inhibited the transfer of educational research findings to translation pedagogy, the increased awareness of the multidisciplinary nature of translation and also the increased involvement in translator education of scholars with experience in other pedagogical domains are breathing fresh life into stifling chalk-and-talk translation classrooms (Colina, 2003; González Davies, 2003, 2004; Kiraly, 1995, 2000; Malmkjær, 1998).

Two increasingly popular pedagogical approaches reflect the increasing application of educational research findings to translation pedagogy. The first is objectives-based instruction, with its special emphasis on the specification of the aims of instruction, the sequencing of tasks and authentic classroom activities (Delisle, 1984; González Davies, 2003, 2004; Hurtado Albir, 1999; Nunan, 1993). Instead of the mere distribution of knowledge, the objectives-based classroom favors the negotiation of knowledge between students and between students and teachers. Instead of random text selection at the whim of the teacher, this approach emphasizes the consistent use of carefully structured syllabi with stated aims and objectives that take into account specific stages of learning.

The other innovative approach is based on constructivism, a family of educational philosophies that has already been applied to a wide variety of educational domains and that is based on the concept that learners essentially construct their own understandings of the world, rather than ingesting ready-made understandings from others, such as teachers. An interpretation and potential applications of a social constructivist approach to translation pedagogy, based on the Vygotskian view that the mental construction process is essentially a social one, are outlined in Kiraly (2000). In a social-constructivist classroom, students construct knowledge and skills through group interaction. Although the earliest stages in the educational process may closely resemble transmissionist teaching, the teacher gradually proceeds to 'scaffold' the instructional process, transferring considerable responsibility for learning to the learners themselves. Starting with consciousness-raising activities, instruction proceeds to simulated small-project work and then authentic projects carried out by the students collaboratively but quite independently of the teacher, who may serve as a resource person and project coordinator. This process is intended to promote students' initiation into the professional world (Kiraly, 1995, 2000; Little, 1991).

Perhaps the most striking change in classrooms from the application of both the objective-based and the social-constructivist approach is the shift toward student-centered learning. Although the chalk-and-talk transmissionist approach may still be the rule in many translator education centers, what might be called cooperative or collaborative approaches involving extensive group work and a systematic transfer of control from the teacher to the learners in the educational process are becoming increasingly popular. Many teachers are seeing their role gradually evolve from that of lecturer to include that of facilitator, advisor, and resource person, from being a 'sage on the stage' to a 'guide on the side.' As for classroom activities and procedures, both of these approaches combine real-life and pedagogical activities, task- and project-based teaching, and portfolios for assessment purposes (González Davies, 2003, 2004; Hurtado Albir, 1999).

Technology and Translation Pedagogy

Some of the most significant changes in the translator's profession over the past 30 years have been the advent of computer-based tools, the impact of globalization, and high-speed, worldwide communications. Whereas translators in the early 1980s were still typing their translations into typewriters and mailing them or delivering them to clients, most translators now work with up-to-date personal computers and transmit their texts almost instantly around the globe. No longer restricted to print dictionaries and texts for reference materials, translators today work extensively with search engines, parallel texts, and glossaries that can be updated at will. They not only process basic texts, but must also work with spreadsheets, desktop-publishing programs, and terminology management programs. Media translation has become increasingly computerized, and software localization comprises an entire subdomain of professional translation. Complex translation memory systems are increasingly becoming the order of the day for translators in many parts of the world (Austermühl, 2001).

A related shift in translator education has been away from an emphasis on general translation skills toward those specifically needed for the translation of specialized or technical texts. With economic globalization and the advent of software and Internet localization, translator trainees are

increasingly in need of research skills, technical knowledge and competence in the use of translation technologies including translation memories and terminology management programs. The curricula of translator education programs have adapted to keep pace with changes on the market, and pedagogical approaches specifically for the training of technical translation skills are starting to emerge as well (Gonzalez Davies, 2003).

The advent of modern electronic tools has not only increased the pace of the translation process, it has also expanded the range of tasks that the translator can be expected to fulfill as well as their professional opportunities. In addition, technological advances and the global village phenomenon have contributed to the crumbling of barriers in international communications and the global marketplace. This in turn has led to an increased awareness of cultural and textual differences as well as of the implications of these advances for the translator's work. Finally, as Kaiser-Cooke (2003) has clearly demonstrated, we have reached a stage in the history of translation studies where translation theory, pedagogy, and practice can inform each other.

The rapid pace of change in the translation profession is certainly having a major impact on translation studies curricula and also on pedagogy to an increasing degree. Perhaps more than for translation skills *per se,* it is self-evident that learners need hands-on experience to develop skill at manipulating the electronic tools that are vital to the profession today. Instructors in the area of computer-aided translation are often experienced translators themselves and see the necessity for practice-oriented work to develop computer proficiency. Although computerized classrooms still lend themselves to transmissionist instruction, with a single computer and LCD display that can allow the teacher to remain in the focus of attention, of especial interest in the future will be efforts to turn the computer-based learning environment into a collaborative learning environment (Kiraly, 2000: 123–139; González Davies, 2004). Thanks to the low cost and ready availability of high-speed digital communications, distance learning and blended learning are also beginning to expand pedagogical options in translation pedagogy (Pym, 2002).

Conclusion

In theory, translation pedagogy has already come a long way from its early exclusive reliance on the lecture format to transfer translation competence from teachers to students. Although in practice the transition process is slow, the writing is on the wall. Translation studies has established itself as an independent, yet multidisciplinary field of study. The 300 translator education programs now need to devote increased attention to the numerous albeit piecemeal attempts to make the development of translation-related skills a process of increasing linguistic, technical, and social competence and professionalism. As the title of a recent volume of articles on translation pedagogy reflects, translation pedagogy needs to open the door to the ivory tower (Baer and Koby, 2004). It needs to begin communicating with professional translators on the market as well as researchers and scholars in other fields, and it needs to investigate teaching approaches and techniques to determine the role that state-of-the-art pedagogy can contribute to a field of human endeavor that is both ancient and at the cutting edge of intercultural and interpersonal interaction.

Translation: Pragmatics

X Rosales Sequeiros, University of Greenwich, London, UK

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Pragmatics has become increasingly important in the study of translation. This is the result of a number of shifts in the way translation itself has been approached. This includes, first, the fact that we have begun to look at translation more and more as just another type of language use, indistinct from other ordinary language uses (apart from the fact that it involves two languages). Second, this shift has made it possible to consider translation as falling under the remit of verbal communication, thereby allowing us to study it within pragmatics. Finally, new developments in pragmatics have enabled us to unify the study of all types of language use, including translation, under a single pragmatic theory, thus allowing us both to simplify the study of translation and to bring it closer within the sphere of verbal communication. The end result of these shifts has been that translation now is seen as just one more instance of verbal communication and consequently, as being subject to the same principles of verbal communication that govern all utterance interpretation (both intra- and interlinguistically). (*see* **Intercultural Pragmatics and Communication**.)

The shifts in the overall approach to translation have only taken place very gradually over the last 20 years or so and in the context of an unsystematic and fragmented study of translation. This entry reviews these changes and discusses how pragmatics has come to solve earlier problems and to play an increasingly central role in the discipline. (*see* **Pragmatics: Overview**.)

The article is organized as follows. First, the gradual shift toward pragmatics within translation is discussed briefly. Then, some of the current key pragmatic concepts, as applied to translation, are introduced. Finally, the results are discussed, and some conclusions are drawn.

A Brief Overview of Approaches to Translation

The study of translation has traditionally been approached from two different points of view: one is non-theoretical, the other more theoretically oriented (for an introduction to translation studies, see, e.g., Munday, 2001).

The non-theoretical approaches to translation maintain that translation is not primarily an act of communication, but rather an art, an intuitive endeavor, and that as such is not amenable to scientific treatment. This is the stance taken by a scholar such as Steiner, who argues that in translation "what we are dealing with is not a science, but an art" (1975: 295). Similarly, Newmark (1988: 19) argues, "[i]n fact translation theory is neither a theory nor a science, but the body of knowledge that we have and have still to have about the process of translating." These non-theoretical approaches have been very influential in the study of translation, in that many scholars have seen their role as restricted to the production of lists of recommendations that could guide translators in their work. However, it has been generally acknowledged that one of the main problems with this type of approach is its inherent limitation as regards scientific enquiry and as to the type and degree of explanation achievable. In other words, from this point of view, at most we are likely to achieve a set of observations about

Introduction

Pragmatics has become increasingly important in the study of translation. This is the result of a number of shifts in the way translation itself has been approached. This includes, first, the fact that we have begun to look at translation more and more as just another type of language use, indistinct from other ordinary language uses (apart from the fact that it involves two languages). Second, this shift has made it possible to consider translation as falling under the remit of verbal communication, thereby allowing us to study it within pragmatics. Finally, new developments in pragmatics have enabled us to unify the study of all types of language use, including translation, under a single pragmatic theory, thus allowing us both to simplify the study of translation and to bring it closer within the sphere of verbal communication. The end result of these shifts has been that translation now is seen as just one more instance of verbal communication and consequently, as being subject to the same principles of verbal communication that govern all utterance interpretation (both intra- and interlinguistically). (*see* **Intercultural Pragmatics and Communication**.)

The shifts in the overall approach to translation have only taken place very gradually over the last 20 years or so and in the context of an unsystematic and fragmented study of translation. This entry reviews these changes and discusses how pragmatics has come to solve earlier problems and to play an increasingly central role in the discipline. (*see* **Pragmatics: Overview**.)

The article is organized as follows. First, the gradual shift toward pragmatics within translation is discussed briefly. Then, some of the current key pragmatic concepts, as applied to translation, are introduced. Finally, the results are discussed, and some conclusions are drawn.

A Brief Overview of Approaches to Translation

The study of translation has traditionally been approached from two different points of view: one is non-theoretical, the other more theoretically oriented (for an introduction to translation studies, see, e.g., Munday, 2001).

The non-theoretical approaches to translation maintain that translation is not primarily an act of communication, but rather an art, an intuitive endeavor, and that as such is not amenable to scientific treatment. This is the stance taken by a scholar such as Steiner, who argues that in translation "what we are dealing with is not a science, but an art" (1975: 295). Similarly, Newmark (1988: 19) argues, "[i]n fact translation theory is neither a theory nor a science, but the body of knowledge that we have and have still to have about the process of translating." These non-theoretical approaches have been very influential in the study of translation, in that many scholars have seen their role as restricted to the production of lists of recommendations that could guide translators in their work. However, it has been generally acknowledged that one of the main problems with this type of approach is its inherent limitation as regards scientific enquiry and as to the type and degree of explanation achievable. In other words, from this point of view, at most we are likely to achieve a set of observations about

translation; there will not be any systematic development of an underlying theory that would allow us fully to explain the phenomena involved in translation. Inevitably, as communication plays no central role in these non-theoretical approaches, the contribution of pragmatics is limited.

The more theoretically oriented approaches to translation have attempted to solve the inherent limitations of non-theoretical accounts. Broadly speaking, two types of approach can be identified: the first type is multidisciplinary and the second equivalence-based. The multidisciplinary approaches have tried to consider the various influences that can be observed in translation, with a view toward shedding some light on the processes involved. They have attempted to do this by exploring the impact on translation of diverse disciplines such as linguistics, literature, cultural studies, anthropology, etc. Multidisciplinary approaches have been influential in opening up the study of translation to many disciplines and in enabling researchers to explore a wide range of influences on the process of translation. However, one of the main problems with this type of approach has been the lack of a coherent and systematic account, giving rise instead to a highly fragmented study of the discipline and to inevitable limitations in the development of a unified theory of translation. Within this type of approach, the role of pragmatics has, at best, been one among many contributions to the field; pragmatics has not played any systematic or central part in its development.

The first major approach that allowed us to develop a more systematic and coherent account of translation was one based on the notion of equivalence (for an introduction, see Baker, 1992). This approach is part of an array of theories that are ultimately based on a structuralist view of translation and on the code model approach to communication (for an introduction to some of these theories, see Munday, 2003). The equivalence-based approach involves an important theoretical shift in that it is one of the first major attempts not only to develop a systematic and explanatory account of translation, but also to include explicitly the role of pragmatics in translation (in particular, Gricean pragmatics). (*see* **Grice, Herbert Paul (1913–1988); Pragmatics: Overview**.) Equivalence, in the context of translating, implies that the aim of a translation is to produce a target language text which is equivalent to the original language text. This represents an improvement on earlier approaches in that here there is a purpose and a guiding principle in the production of translations, as well as an explanation for the choices made by a translator, both in the process of translation and in the production of target texts.

The equivalence approach to translation has also been influential in that it has enabled practitioners to apply more consistent criteria to the study, practice, and evaluation of translations. From a pragmatic point of view, it has made it possible to include equivalence features at the pragmatic level (such as reference, coherence, implicatures, pragmatic maxims, etc.). (*see* **Cohesion and Coherence: Linguistic Approaches; Maxims and Flouting; Implicature**.)

Even so, the equivalence approach, systematic as it may seem, lacks definitional precision. Baker herself, whose entire 1992 book is based on the notion of equivalence, acknowledges the shortcomings of this concept: "equivalence is adopted [...] for the sake of convenience – because most translators are used to it rather than because it has any theoretical status." (Baker, 1992: 5–6). The approach has also been shown to face other serious problems (see Gutt, 2000: Chap. 1), particularly as a result of the insights gained in current studies in pragmatics and human communication. What these problems have in common is the insight that equivalence is at best a descriptive concept, not an explanatory one, and that it ultimately relies on other concepts that are external to its definition (i.e., equivalence is not a sufficient criterion in and by itself). So how can these problems be addressed?

Translation, Communication, and Pragmatics

A suggested solution to the problems mentioned above places the study and practice of translation more firmly within verbal communication and pragmatics (thus making it more amenable to scientific study). As Hatim and Mason (1997: vii) state, "we look at all kinds of translating as essentially *acts of communication* in the same sense as that which applies to other kinds of verbal interaction" (my italics). Gutt (2000: 23) argues along the same lines: "Translation is indeed best handled as a matter of communication." He similarly argues that "issues of translation are at heart issues of communication" (Gutt, 2000: 198). This line of enquiry, which sees translation as an instance of verbal communication, is the main link between pragmatics and translation in current research on the subject.

The chief proponent of a consistent and systematic application of pragmatics to translation has been Gutt (2000), who has applied one of the main current pragmatic theories, viz., Relevance Theory, to the subject (for an introduction to Relevance Theory, see Blakemore, 1992; Sperber and Wilson, 1995). (*see* **Relevance Theory**.) Relevance Theory allows us to approach the study of translation as an act of

communication, in a systematic and explanatory fashion. A number of key assumptions make this possible. As Blakemore (1992: 39) argues, "[t]he search for relevance is something that constrains all communication, verbal and non-verbal." (Gutt, 2000: 198) goes further and maintains that "the principles, rules and guidelines of translation are applications of the principle of relevance." He further claims that "given the general framework of relevance theory, no special, additional concepts or theoretical tools are needed to accommodate translation" (Gutt, 2000: 237). The latter claim has profound and far-reaching implications for translation, as it amounts to saying that there is no need for a theory of translation as such. Instead, translation is seen as just one more instance of verbal communication, with the particularity that it involves two languages. Thus, from this point of view, translation can be studied fully within pragmatics (which thereby becomes its proper theoretical domain).

There are a number of advantages of this approach over earlier ones. First, there is no need to construct extra theoretical machinery to account for translation. Second, all the separate and diverging claims that have been made about translation can be seen as natural applications of the principle of relevance and, therefore, can be unified under a single explanatory theory (rather than being isolated claims without internal theoretical foundation or coherence). (*see* **Communicative Principle and Communication**.) Third, translation can benefit directly from advances made in our understanding of verbal communication, pragmatics, and cognition (which contrasts with the earlier situation, when translation was treated as an isolated discipline and had to borrow concepts from widely diverging areas of research, something that resulted in the absence of a unified account). Finally, in contrast with, e.g., equivalence approaches, an approach based on Relevance Theory provides explicit definitions for its theoretical framework, which is intended to be universal in its application and univocal in its search for intended interpretations of texts/discourses.

For a translation theory based on the notion of relevance, the challenge has been to spell out the implications for translation of all of the above claims as well as of the specific theoretical claims made within Relevance Theory proper. So far, two areas of research have been developed in this respect: one at the macro level and the other at the micro level. By far the biggest contribution in this endeavor has been achieved at the macro level (see, in particular, Gutt, 2000); here the driving interest has been the theoretical characterization of translation as an instance of verbal communication to be studied within pragmatic theory. In this respect, Gutt (2000) argues that the key notion in any account of translation is that of resemblance, both interpretive and non-interpretive. He claims that for a target text or discourse to be a translation, it has to enter into a relationship of resemblance with the original text/discourse (in which resemblance is defined as the extent to which two representations share properties such as semantic content, linguistic features, sounds, etc.). In particular, the main focus of research has been interpretive resemblance, which focuses on the resemblance of content between original and target texts (i.e., the extent to which they share analytic and synthetic implications). For a translation to be successfully communicated, so it is claimed, it must (interpretively) resemble the original in an optimally relevant way. More recently, researchers such as Almazán García (2001) have argued that the notion of interpretive resemblance must be substituted by that of meta-representation in order to cover all possible cases of translation. However, as matters stand, there does not seem to be enough evidence to suggest that the notion of resemblance should be unable to by itself account for all translation cases (cf. Gutt, 2000: 198).

There are a number of advantages in characterizing translation as interlinguistic resemblance within the approach provided by Relevance Theory. For example, such a characterization allows us to understand why some translations are more direct than others (e.g., when issues of close resemblance are relevant, as in literary translation); or why it is sometimes necessary to include background information in the target text (e.g., when contextual assumptions would not otherwise be available to trigger the intended contextual effects, as in translation across very different cultures). Thus, research at this macro level has been fundamental to the application of pragmatic theory to translation; it also has made its application possible at the micro-level.

At this level, the prevailing interest has been to explore in more detail the processes and products that result from seeing translation as an act of communication (see, e.g., Rosales Sequeiros, 2002). Here, a key assumption is that the translator is not only a receptor of the original text but also a communicator of the target text. This presents us with a double role for the translator in communication, which (together with the gaps that necessarily exist between what is encoded and what is communicated in linguistic communication) gives rise to an array of textual and communicative effects in translation (e.g., discrepancies between original and target texts). These effects can be seen at all pragmatic levels, including the word/concept level, the referential level, the propositional

level, and the level of implicature, among others. In all these cases, we find that translations often differ from the original texts as a result of the communicative processes experienced by the translator during the interpretation of the original text and the rendering of his/her interpretation in the target text. In these cases, we find that pragmatic theory allows us to explain the discrepancies found between the two texts and, in turn, helps us in our evaluation and acceptability judgments of target texts. This insight also allows us to understand and unify, within a single theory, a wide range of translation discrepancies. For example, it allows us to determine when direct translations are not possible (e.g., when the linguistic structures of the two languages are not capable of the same degree of explicitness); or why certain discrepancies recur in translation (e.g., when the translator renders into the target language not what is encoded in the original text but, rather, what is communicated). In general, research at the micro level allows us to understand and predict the potential problems faced by translators in the process of translation, and thus alert practitioners to possible solutions.

Conclusion

Seeing translation as an instance of language use, and consequently studying it within the framework of verbal communication and pragmatics, has resulted in pragmatics playing an increasingly important and central role in the study of translation. This shift, as well as other current developments within pragmatic theory, has enabled us to unify the study of translation within a single theoretical approach, viz., that of Relevance Theory.

Relevance Theory allows us to simplify the study of translation both by doing away with the need for a separate theory of translation and by allowing us, instead, to indistinctly apply the same concepts used in other types of language use to translation. Translation is specific only inasmuch as it involves two languages and inasmuch as the target text is purported to resemble the original text. These contextual assumptions play the same role in the interpretation process as does any other contextual assumption. All the other observable and cognitive processes involved in translation can be explained and accounted for by pragmatic principles and processes covered within Relevance Theory.

Within the relevance-theoretic approach, research on translation has focused on two main areas. On the one hand, there has been an interest at the macro-level in characterizing translation as a communicative event involving interlinguistic resemblance between two texts or discourses. On the other hand, there has been an interest at the micro level in understanding the cognitive and communicative processes experienced by translators as receptors and communicators, and the effects these processes have on the products of translation.

Future pragmatic research on translation is likely to continue to focus on the two levels indicated above, as it attempts both to specify the communicative nature of translation more precisely and to understand the changes in target texts and discourses caused by the communicative process of translation.

Translation: Profession

G Samuelsson-Brown, Bracknell, Berkshire, UK

© 2006 Elsevier Ltd. All rights reserved.

Present Status

The translation profession is undergoing significant change and is becoming increasingly structured with more and more students attending undergraduate and postgraduate translation courses at universities. People who have trained in other professions are retraining as translators partly to specialize and partly to make a career move as a way of finding enhanced career satisfaction. A significant proportion of translators work as freelancers and therefore have the opportunity to wrap their careers around their own lifestyles and family commitments. Few professions offer this level of flexibility and independence.

Although the professions of translator and interpreter are significantly different, you can hear interpreters being called translators in news reports from around the world. Many people work as translators and interpreters since both have common skills. In simplistic terms, a translator produces a written text in what is referred to as a target language that is a true and faithful rendering of a text supplied in a source language. Interpreters provide verbal translation into and from source and target languages.

It is usual practice for a translator to work into his or her target language, and professional ethics recommend that this should be the translator's mother tongue or language of habitual use, as it is sometimes called. However, circumstances often mean that this is not possible. I have taught on short courses for translators who work under extraordinary conditions in conflict areas or in government offices where they are required to translate into several target languages purely because of the extreme demands of their circumstances or the highly confidential nature of their work.

Translators have the luxury of being able to consider and revise their work, usually several times, before submitting it to their client. Translators can take a break when they feel like it – subject to the urgency of work, of course. There is physical evidence of the translator's work in most cases. Interpreters, on the other hand, have but a single stab at translation, and their output is verbal with little opportunity for revision. Physical evidence is provided only if their work is recorded or a third person produces a written report of the same.

It is easy to blame the translator for other people's errors. "Lost in translation" is an easy excuse, and the quality of the source material and information provided by the client usually has a far greater impact on the quality of the output than the work of the translator. The translator is often given scant regard in management literature. Just to give an example, the bold statement, *"Translation errors are the cause of the greatest number and variety of blunders in international business"* is the opening line of the chapter on translation in a book on blunders in international business (Ricks, 1993: 77). This gives no indication of the quality of the source material, the way in which the translator is selected, or the constraints he or she works under, all of which have a significant effect on the quality of the end result.

At present translation is an unregulated profession since anybody can call themselves a translator without having formal and recognized qualifications. Translation is often a cost-led business where price may determine the quality of the output. This state of affairs will continue until the translation profession is taken seriously and people who are engaged to do translation work have appropriately recognized qualifications. Culture plays a part, and the status of

I have taught on short courses for translators who work under extraordinary conditions in conflict areas or in government offices where they are required to translate into several target languages purely because of the extreme demands of their circumstances or the highly confidential nature of their work.

Translators have the luxury of being able to consider and revise their work, usually several times, before submitting it to their client. Translators can take a break when they feel like it – subject to the urgency of work, of course. There is physical evidence of the translator's work in most cases. Interpreters, on the other hand, have but a single stab at translation, and their output is verbal with little opportunity for revision. Physical evidence is provided only if their work is recorded or a third person produces a written report of the same.

It is easy to blame the translator for other people's errors. "Lost in translation" is an easy excuse, and the quality of the source material and information provided by the client usually has a far greater impact on the quality of the output than the work of the translator. The translator is often given scant regard in management literature. Just to give an example, the bold statement, *"Translation errors are the cause of the greatest number and variety of blunders in international business"* is the opening line of the chapter on translation in a book on blunders in international business (Ricks, 1993: 77). This gives no indication of the quality of the source material, the way in which the translator is selected, or the constraints he or she works under, all of which have a significant effect on the quality of the end result.

At present translation is an unregulated profession since anybody can call themselves a translator without having formal and recognized qualifications. Translation is often a cost-led business where price may determine the quality of the output. This state of affairs will continue until the translation profession is taken seriously and people who are engaged to do translation work have appropriately recognized qualifications. Culture plays a part, and the status of

the translator depends on achievement-oriented and ascription-oriented cultures. In Western society, the translator is supposed to be a neutral black box serving the interest of modern language comprehension, whereas in Japan, for example, the translator is an interpreter not simply of language but also of gesture, meaning and context (Trompenaars and Hampden-Turner, 2002: 110).

Stakeholders in the Profession

It is heartening to recognize that, over the last 20 years or so, clients' attitudes toward translators and the profession have changed. There is a growing acceptance, at least among more enlightened clients, that the translator is a professional and not just an anonymous black box impersonally churning out texts in a target language. Table 1 identifies some of the stakeholders in translation and their impact on the profession and the quality of its work.

Continuous Personal Development

The translator becomes quite erudite by virtue of having to read word for word and fully comprehend the material he or she translates. Although this is educational to a degree, there is no substitute for sound subject knowledge. Continuous personal development is now a reality in the translation profession, but how is this achieved? The advent of the World Wide Web makes researching subjects for translation more accessible. The only caution is that information gained from this source may not necessarily be validated. So what other options are available?

Finding Good Mentors

I became a translator by circumstance rather than design and the fact that I had a technical background. I was living in Sweden at the time and had received what might be termed a science-based education.

Table 1 Stakeholders in translation

Stakeholder	*Impact on the profession*
The translator	The translator has a responsibility to his or hers clients and to the profession as a whole. Only by being completely professional and regulated can the translator and the profession gain the recognition and status they deserve.
The client/end user	The client/end user is often quite unaware of the true demands of the profession and holds a stereotypical view of how the translator works. The layperson invariably imagines that the translator translates into 'foreign' languages and has little idea of the skills required to be a translator. Thus the translator and the profession have the daunting task of educating clients, raising awareness, and dispelling stereotypical views.
Translation agencies	Serious translation agencies now employ project managers, who are linguistically skilled and, in many cases, will have completed translation studies at a university. This represents a change from the time when translation project management was purely an administrative exercise that provided little added value from a translation aspect.
Public bodies	The European community and the United Nations are among the organizations that hold translation competitions for translators. Each demands a degree either in languages or a specialized field as well as ''*a perfect mastery of their mother tongue*'' (European Community) or ''*a perfect command of English and an excellent knowledge of French and one of the other official languages of the United Nations*'' (United Nations) (Samuelsson-Brown, 2004:20). Although this might be considered overkill for the profession, as a whole it sets a good benchmark.
Education providers	The number of universities that teach translation and translation studies has grown. These offer a range of options that can help would-be translators identify their potential specialist interests. Those who follow postgraduate studies have the opportunity to compile a translation dossier under the guidance of experienced practitioners. This provides evidence of their skills and facilitates entry into the profession by helping surmount one of the most difficult hurdles when starting out – ''How can I get work if I have no experience but how can I gain experience if I cannot get work?''
Professional organizations for translators	No professional organization can survive without serving the best interests of its members and, consequentially, enhancing the status of its members in the public eye. In the United Kingdom the Institute of Linguists and the Institute of Translation and Interpreting have become aware of the need for and support the concept of continuing personal development. This can only enhance the status of the profession and emulate the practice already implemented by other professions, such as doctors, accountants, and solicitors. The Institute of Translation and Interpreting has a mentoring program where fledgling translators can seek the advice of more senior and experienced members. This is managed through having an e-mail forum and mentees being set personal development assignments for discussion with other mentees and experienced mentors. In 2004, the Institute of Linguists sought chartered status for its members and the profession. This is an important step on the way to regulating the profession and thus enhancing its status.

Moving into translation seemed a natural progression. As a staff translator/technical editor, I was fortunate at the time to be working with a group of specialists that included technical writers who were experts in their own particular fields. They were able to act as guides and mentors in terms of subject knowledge. As a naïve, fledgling, and perhaps ignorant translator, I felt undaunted by the texts offered to me for translation. As I became more experienced, I accepted that I have limitations – difficult to accept when trying to build a reputation.

Translator organizations such as the Institute of Translation and Interpreting run short courses and seminars on specific subjects as well as a program in which experienced members act as a mentoring group.

Further Education

Attending further education on a full-time basis is not always practical or affordable. Distance learning is a viable option and allows the translator to further his or her education while still working and earning a living. Distance learning has developed significantly over the last 30 years through organizations such as the Open University. Though this demands considerable discipline in managing the time required to study, my personal experience of this type of continuing personal development is nothing but positive. It also offers networking and marketing opportunities through meeting other mature students who are already established in their own careers. This is positive since many translators, and freelancers in particular, live a hermit-like existence and do not mingle with the 'outside world' enough.

The concept of continuing personal development is in itself a development and evolves from attending discrete courses to encompassing planned development rather than reacting to needs at a particular time.

Quality Control

This subject is a minefield since translation is intellectual output based on individual interpretation and style – the latter is also the greatest source of dispute. There is no formal requirement for translators to have an accredited quality management system such as ISO 9001:2000. It can be argued that such accreditation applies only to the administrative and management procedures related to the production and delivery of a translation and not to the translation process itself. This is true to a degree, but this latest version of the standard is more client-oriented, and the self-analysis the standard demands is a useful discipline.

The act of writing procedures to analyze product realization and deal with client complaints, for example, raises awareness of quality management and professional responsibilities toward the client. Part of my own quality control is to grade the quality of source material submitted for translation and provide constructive feedback to clients (with the appropriate level of sensitivity) in an attempt to ensure that the texts I am asked to translate do not contain mistakes that can be misinterpreted or perpetuated in the translation.

Admittedly, the compilation of a quality manual takes time, and maintaining accreditation costs money. Documenting a quality management system does have a number of benefits. For example:

- Formal accreditation according to ISO 9001:2000, or having a documented quality management system, may be a requirement when being considered for certain translation assignments.
- Being accredited can provide a competitive advantage.
- Analysis of what could diminish quality of the end product raises awareness and, consequently, goes a long way to pre-empting problems.

Unless stated otherwise by the client, the normal assumption is that the translation is being made for information purposes. Quality objectives determined by the intended use of the translation and general objectives are illustrated in Table 2. These are provided for guidance only.

Table 2 Quality control objectives

Quality control objectives	*Intended use of the translation*			
	Information only	*General publication*	*Legal*	*Certified translation*
To provide the appropriate linguistic skills and experience	✓	✓	✓	✓
To provide an accurate and complete translation	✓	✓	✓	✓
To deliver on or before the agreed delivery date and time	✓	✓	✓	✓
To deliver work in the software format prescribed by the client	✓	✓	✓	
To adhere to the style and layout prescribed by the client		✓	✓	✓
To use terminology appropriate for the intended use	✓	✓	✓	✓

Conclusion

Looking back at attitudes in the 1970s and 1980s, translators were insular and considered any criticism (albeit constructive) as an affront to their competence as a translator. The concept of planned continuing personal development had not been considered. Technology has changed almost beyond recognition, as has the way in which most translators work. Although I am heartened by the way in which the profession is developing, translators need to realize their true worth and promote themselves as professionals if they are to receive just rewards for their labors.

Translation Units

K Malmkjær, Middlesex University, London, UK

© 2006 Elsevier Ltd. All rights reserved.

The Unit of the Translation Product

The definition and identification of the unit of translation depends on whether the translation product or the translation process is being considered. When the translation product is at issue, translation units are pairs of source and target text segments (*see* **Translation Memories**); these segments can be identified as source and translation by mapping the units of the target text onto the units of the source text (Toury, 1986). Studies that have compared translation and source text pairs produced by novice translators with pairs produced by experienced translators show that the units formed in novice-translator pairs are smaller in extent and generally are of a lower linguistic rank (word, phrase) than are those (clause, sentence) formed in pairs produced by experienced translators.

The Unit of the Translating Process

When the process of translating is at issue, the translation unit is understood to be that stretch of the source text that the translator keeps in mind at any one time, in order to produce translation equivalents in the text he or she is creating (Lörscher, 1991). These units can be identified during 'talk aloud protocol' studies (TAPs) (*see* **Think-Aloud Protocols**), and, like the product-oriented studies, TAPs suggest that whereas learner translators tend to view a word or a phrase as the unit of translation, more experienced translators focus on larger stretches of text as translation units. Note in this connection that some research suggests that the verbalization process of TAP studies has a shortening effect on translation units.

Translation Units and Translation Equivalents

Translation units (however understood) cannot be identified with translation equivalents, for two reasons. First, the former regularly determine the latter; second, whereas translation equivalents, being formal, may be fairly fixed for some expressions, translation units, in the cognitive sense of units of attention, tend to vary according to the translator's personal past history and general mental capacities. Consider the potential text segments 'six' and 'feet' cooccurring in the uninterrupted sequence, *six feet*. The translation equivalent for the two-word sequence will tend to vary depending on the cotext in the sentence; in this case, the choices may be between the body-part sense of 'feet' and the unit of measurement. Thus, before an equivalent can be selected, it is necessary to consider at least the stretch of cotext that explains which sense is meant, and that stretch will then be the translation unit. Potential units in the example here might be 'all of its six feet' in a sentence such as *The monster put socks on all of its six feet*, and 'six feet tall' in *Jack is six feet tall*. If the unit initially identified as instrumental in determining where equivalence is to be established and what it is to be were in fact 'six feet tall,' then, as far as a translator *in medias res* is concerned, it may be necessary to break this unit down into two smaller units, namely, 'feet' and 'six,' so that a measurement

Translational Equivalence

S L Halverson, University of Bergen, Bergen, Norway

© 2006 Elsevier Ltd. All rights reserved.

Introduction

The concept of equivalence can be identified as one of the most contentious, and thus potentially most significant, concepts in the study of translation. Debates have centered on how the concept is to be interpreted, the domain of its application, and the extent to which it is even useful in the study of translation.

In understanding the controversy, it is helpful to keep in mind the basic components of the concept of equivalence. 'Equivalence' is defined as the state of being 'equivalent,' which, in turn, is defined in the *Collins English dictionary* (1986: 516) as being, among other things:

1. equal or interchangeable in value, quantity, significance, etc., or
2. having the same or similar effect or meaning.

As suggested by these two main entries, the concept includes three key elements: two entities between which a relationship holds, a relationship (of equality, interchangeability, sameness, similarity), and a quality or feature according to which the relationship between the two elements is defined (e.g., value, quantity, significance, effect, meaning, etc.). As we shall see, various elements of this notion will be more or less in focus in the evolving debates. However, there has been no disagreement on the basic content of the notion.

The following presentation includes a brief historical overview of the development of the equivalence concept in translation studies. Next, two complementary views of this historical development are presented. In the final section, the *status quo* will be briefly sketched.

A Brief Historical Overview

Chesterman (1998: 16–27) provides an insightful chronology of the debate on equivalence in translation studies. In his account, Chesterman describes three distinct stages in the historical development. These three stages coincide in large part with the key stages discussed in Pym (1995) and Halverson (1997). In the following, Chesterman's outline will serve as the starting point, and the contributions of the latter two will be addressed in the section on the development in context.

Chesterman distinguishes between the 'equative view,' 'the taxonomic view,' and 'the relativist view' of equivalence, in chronological order. The oldest, the equative view, "is based on the original mathematical definition of equivalence, denoting a reversible relation: A is B and B is A" (1998: 18). This view has been linked to the earliest known (more specifically Western) writings on translation, and "appears to have been heavily influenced by the uses to which translation was put at the time, and other more general beliefs of the scholars who thought about these matters" (ibid.). The claim is that, in the Western tradition at least, the primary concern and problem of translation scholars was the translation of the Bible. Concurrent beliefs in the inviolate nature of the particular meaning of this particular text ('the Word of God') and in the separability of form and meaning led to a theory of translation in which meaning was believed to be identical in source and target texts. Equivalence of source and target was, in this view, a unitary notion. There was only one kind of relationship that could pertain between a translation and its source: identity of meaning (the relationship is identity and the feature compared is meaning).

The second stage, represented by the taxonomic view in Chesterman's terms, is one of more recent significance. In brief, the main development signaled by this view was that equivalence is not a unitary notion, but a multiple one; in other words, there is not one kind of equivalence, but many. According to Chesterman (1998: 21), the earliest signs of this view are visible even in Jerome. However, the main elaboration of this view came with the emergence of translation studies as an independent academic discipline, a development which started in the 1960s.

Several scholars have elaborated types of equivalence, though not all have achieved the same theoretical status. One of the first, and most influential, is Nida's (1964) distinction between 'formal' and 'dynamic' equivalence. Nida discusses the two types as 'two basic orientations in translating.' The first, formal equivalence, is described as follows:

> Formal equivalence focuses attention on the message itself, in both form and content. In such a translation one is concerned with such correspondences as poetry to poetry, sentence to sentence, and concept to concept (1964: 159).

In a translation oriented toward dynamic equivalence, on the other hand,

> . . . one is not so concerned with matching the receptor-language message with the source-language message, but with the dynamic relationship, that the relationship between receptor and message should be substantially the same as that which existed between the original receptors and the message (ibid.).

Nida's approach maintains a focus on a sameness relationship between source text and target text, and in this respect maintains two of the three key components of the equivalence concept as it was previously known. What changes the debate is the introduction of text-external factors. His distinction between formal and dynamic equivalence establishes a new feature upon which to base a sameness relationship: the idea of receptor effect. Here the grounds for establishing sameness are located outside the texts themselves, with respect to both their formal and semantic characteristics. The focus is shifted toward their reception.

One of Nida's contemporaries, J. C. Catford, is also concerned with source text (ST)-target text (TT) correspondences and relationships. Catford distinguishes first between 'formal correspondence' and 'translation equivalence,' and in the case of the latter, he makes a further distinction between "translation equivalence as an empirical phenomenon" and "the underlying conditions, or justification, of translation equivalence" (1965: 27). For the purposes of this brief overview, it is important that we note the ways in which source and target language correspondences (formal) differ from ST-TT ones (textual). According to Catford:

> A textual equivalent is any TL text or portion of text which is observed on a particular occasion, by methods described below, to be the equivalent of a given SL text or portion of text. A formal correspondent, on the other hand, is any TL category (unit, class, structure, element of structure, etc.), which can be said to occupy, as nearly as possible, the 'same' place in the 'economy' of the TL as the given SL category occupies in the SL (1965: 27).

Catford (1965: 49) requires further that any given TL item meet certain conditions if it is to be considered a translation equivalent of a given SL item. He claims that, "The SL and TL items rarely have 'the same meaning' in the linguistic sense; but they can function in the same situation." He elaborates on situational sameness by saying that it is established on the basis of overlapping contextual or 'situational features,' analogous to the distinctive features of phonology. For the purposes of our historical overview, it is important to note that Catford too claims a central role for translation equivalence. His project incorporates a sameness relationship between ST and TT elements, and the basis for sameness is 'features of situational substance.'

A third taxonomic approach is represented by Newmark (1982, 1988). His contribution to the equivalence debate also consists of a distinction between two basic translation 'methods': 'semantic' and

'communicative' translation (1988: 45ff.). These two represent the middle ground on a continuum from SL emphasis to TL emphasis, and the main difference between the two lies in the basis for the 'sameness' relationship. According to Newmark:

> Communicative translation attempts to produce on its readers an effect as close as possible to that obtained on the readers of the original. Semantic translation attempts to render, as closely as the semantic and syntactic structures of the second language allow, the exact contextual meaning of the original (1982: 39).

The focus in communicative translation is, like in Nida, on sameness of 'effect.' In Newmark's semantic translation, the focus is on sameness of 'contextual meaning.' In fact, Newmark's account contains far more detail and more subtle distinctions than this brief presentation allows. But for the purpose at hand, what is vital is the position of Newmark, like Catford and Nida, within the taxonomic tradition in which translation equivalence is considered primary and the objective of translation scholars is to elucidate the grounds on which sameness of ST/TT elements may be established.

A more recent and more elaborated view of translation equivalence is presented in Koller (1995, 2001). Koller argues that an account of translational relationships must take into account five 'equivalence frameworks': extralinguistic content, connotations, text and language norms, the receiver, and certain formal-aesthetic features of the SL text (1995: 197–198; 2001: 214ff.). These five frameworks are then linked to five types of translation equivalence: denotative, connotative, text-normative, pragmatic, and formal, respectively. This is an elaboration of earlier views, in that particular care is given to features of the communicative situation, and it becomes possible to situate the idea of the 'intended effect' in a broader linguistic framework. In terms of the development of the equivalence concept in translation studies, Koller's approach represents expansion, or elaboration, along the feature/characteristic axis. Otherwise, it is fundamentally the same as the other taxonomic views, in that there is a sameness relationship between two texts or text-elements.

The authors mentioned here all share the view that equivalence is central to any description or explanation of translational phenomena. More specifically, they see this notion as one of the defining characteristics of translated texts. In other words, the taxonomies of equivalence types represent criteria for the identification of texts as translations and, in some cases, as good or bad translations.

Chesterman (1998: 24ff.) refers to the third phase in the history of 'equivalence' in translation studies as the 'relativist view.' The emergence of this view is in many ways a much more radical development than the transition from a unitary 'meaning identity' to a richer taxonomic account of sameness. The views within this third stage vary from a complete rejection of the equivalence concept to a radical rethinking of it. For some scholars, the idea of equivalence in translation is philosophically untenable, given the instability of meaning (for an overview see Gentzler, 1993: 144–180). For others, the impetus for rejecting the notion is less philosophically motivated. Following a review of the uses of the concept in translation studies, Snell-Hornby (1988: 13–22) concludes that:

> . . . equivalence is unsuitable as a basic concept in translation theory: the term *equivalence,* apart from being imprecise and ill-defined (even after a heated debate of over twenty years) presents an illusion of symmetry between languages which hardly exists beyond the level of vague approximations and which distorts the basic problems of translation. (1988: 22)

In Snell-Hornby's view, the proliferation of equivalence types (taxonomies) and the loosening of the 'identity' or 'sameness' relationship is indicative of a problem with the concept itself, which leads her to advise against its use.

For other scholars, the focus on ST-TT relationships represented by the taxonomic approach has been maintained, but relativized. The key figure in this movement is Toury, who argues that translations must be identified, not on the basis of predefined relationships, but on the basis of status as such in a target culture (1980, 1995). In other words, 'assumed translations,' those accepted as such by a target culture, are to serve as the sources of information about translational relationships, which are thus empirically grounded and culturally/temporally situated. The crucial step here is that the nature of the translation relationship is no longer predefined; it is empirically derived. Consequently, defining ways in which ST and TT might be the same (types of equivalence) is moot, and the job of the translation scholar becomes to describe the actual relationships found. In terms of the general definition of equivalence that we started out with, we are now left with no specification of the nature of the relationship or the features along which it may be established; the constant is that there is some relationship (Toury's relationship postulate) involving some 'shared features' (Toury's transfer postulate) between the assumed translation and a source text (Toury's source postulate). Thus, what remains is the skeletal definition we started out with: the two entities, a relationship of sharing, and something shared (some feature or features). Within descriptive translation studies, all aspects of the translation relationship

are subject to empirical investigation; nothing is set *a priori*.

The Development in Context

Pym (1995) and Halverson (1997) present two different and complementary accounts of the historical development sketched above, more specifically, the movement from what Chesterman refers to as 'the taxonomic' to 'the relativist' view. In both accounts, the emergence of the taxonomic view in the 1960s and 70s and its rejection by various scholars in the 1980s and 1990s are placed in broader contexts, first in terms of institutional concerns (Pym) and then in terms of philosophical ones (Halverson).

Pym's (1995) account of the rise and fall of the equivalence concept in translation studies was based on an analysis of the sociological/political atmosphere in which translation studies emerged. In his view, for the early scholars (1960s and 1970s) the concept functioned as 'a piece of scientific capital' (1995: 159), which served one major overarching purpose: it gave translation studies scientific legitimacy. According to Pym, "It provided the foundation for research programmes supposedly useful for both machine-translation research and translator training .... the equivalence paradigm enjoyed a degree of success in advancing the cause of moderately independent research programmes and translator-training institutes." (ibid.) According to Pym, the cultural and academic climates of the time were conducive to this development.

Pym also discusses the reversal in the concept's fortunes represented by the relativist approaches. In his account, the historical-descriptive approach represented by Toury, and the philosophically similar scopos theory (Vermeer, 1989), also have clear scientific ambitions; it is just that the equivalence concept was not assigned the pivotal status it had held earlier (Pym, 1995: 160). For both of these theorists, the relationships between source and target texts can be many, and they can only be described after the fact. In other words, translational relationships (whatever they are) are situated in time and space and may show variation across either or both.

Halverson (1997) also addresses the same development, from Chesterman's taxonomic to relativist views of the equivalence concept. Her argument is that this development mirrors contemporary developments in ideas of scientific change and truth. The key change here is from the positivist belief in objectively verifiable truths and science as knowledge accretion to the relativist account of scientific change as historically and socially contingent. Halverson argues that the equivalence concept developed along the same lines; the taxonomic view was based on an objectivist philosophy of science, and the relativist reversal represented a movement toward historically situated contingency. By this account, translation scholars changed as the intellectual climate elsewhere changed.

Status Quo

In his paper, Pym presents evidence of what he calls, "a minority return to equivalence" (1995: 167). He counts himself as one of the "few isolated voices" (1995: 171) calling for a "recupera[tion]" (ibid.) of the equivalence concept. The current situation nearly 10 years after Pym wrote his article is, indeed, one in which several writers argue for a return to the focus on ST-TT relationships and a revitalization of the equivalence concept, broadly defined.

An important work in this connection is Koller's 1995 article, in which he outlines the limitations of the concept of equivalence and neatly demonstrates the gradations of sameness/similarity that pertain between ST-TT pairs. His starting point is the need for a remedy to relativist approaches to defining translation studies' object of study. This article identifies two key features of the current situation: the need for a means to agree on our object of study, and the failure of the equivalence concept to serve that need.

Pym (1995: 165) describes the work of writers such as Gutt (1991), Neubert (1994), and Stecconi (1994) as sharing an interest in "objectifying the subjective" view that equivalence holds an important position in the study of translation. By Pym's account, all of these writers share a concern with creating a framework for a principled investigation of translation, which necessarily involves agreeing on a means of identifying the object of study. For these writers, an appropriate starting point is a revised version of the equivalence concept.

Halverson (1999) takes a similar view with regard to the issue of translation studies' object of study. Her argument is that the concept of 'translation' must be viewed as a prototype concept. From such a perspective, a culturally situated concept/category, with more or less central members, may be related to corresponding categories in other languages/cultures. Halverson (1998, 2002) demonstrates that, at least for some languages, equivalence/sameness/similarity is a vital part of the conceptual content of 'translation.' Thus, the concept, in a graded form, is necessary for translation studies.

The paths forward from the common starting point shared by these authors are less well established; much remains open. In conclusion, one might describe the *status quo* as follows: at present, the equivalence concept is still closely associated with the taxonomic

(objectivist) manifestations of the 1960s–1970s and is, consequently, rejected by many. The emerging interest in a resuscitation founded in different philosophies and/or theories of language is still in the early stages. However, translation studies may be witnessing the beginning of a move away from polarization toward integration on this particular issue.

Introduction

The term 'translational stylistics' was first used by Malmkjær (1994) in the context of a discussion about teaching translation. Nord (1992: 46–47) had earlier distinguished between generalizable and text-specific translation problems that trainee translators might face, suggesting that text-specific problems should be avoided in the early stages of translator training because they allow for less transferability of learning, compared to generalizable translation problems. Students, according to Nord (1992: 47), should "feel free to try out their own creative ways of solving translation problems" only once they have learned "the basic rules of the 'craft.'" Malmkjær (1994: 62) suggested that trainee translators also need to know when the basic rules of the craft need to be followed and when it is better to abandon them and give way to creativity, and that exercises in translational stylistics can sensitize students to the kinds of considerations that are helpful in guiding such decisions. This point was illustrated with reference to the norm that Toury (1991: 188) had referred to as "one of the most persistent, unbending norms in translation in all languages studied so far," namely, the norm that appears to lead to a general tendency to avoid repetition in translations. It is likely that trainee translators internalize this norm during their training period – in any case, given the persistence of the norm, it is clear that translators internalize it at some point in time. However, because repetition is sometimes (perhaps even frequently) used by authors to highlight certain concepts and notions that are important, it may often be

(objectivist) manifestations of the 1960s–1970s and is, consequently, rejected by many. The emerging interest in a resuscitation founded in different philosophies and/or theories of language is still in the early stages. However, translation studies may be witnessing the beginning of a move away from polarization toward integration on this particular issue.

Translational Stylistics

K Malmkjær, Middlesex University, London, UK

Introduction

The term 'translational stylistics' was first used by Malmkjær (1994) in the context of a discussion about teaching translation. Nord (1992: 46–47) had earlier distinguished between generalizable and text-specific translation problems that trainee translators might face, suggesting that text-specific problems should be avoided in the early stages of translator training because they allow for less transferability of learning, compared to generalizable translation problems. Students, according to Nord (1992: 47), should "feel free to try out their own creative ways of solving translation problems" only once they have learned "the basic rules of the 'craft.'" Malmkjær (1994: 62) suggested that trainee translators also need to know when the basic rules of the craft need to be followed and when it is better to abandon them and give way to creativity, and that exercises in translational stylistics can sensitize students to the kinds of considerations that are helpful in guiding such decisions. This point was illustrated with reference to the norm that Toury (1991: 188) had referred to as "one of the most persistent, unbending norms in translation in all languages studied so far," namely, the norm that appears to lead to a general tendency to avoid repetition in translations. It is likely that trainee translators internalize this norm during their training period – in any case, given the persistence of the norm, it is clear that translators internalize it at some point in time. However, because repetition is sometimes (perhaps even frequently) used by authors to highlight certain concepts and notions that are important, it may often be

desirable to re-present repetition in translation; the question facing translators with respect to repetition is when (under which circumstances) to re-present source text-situated repetition in a translation.

A comparison of Hans Christian Andersen's story (1835) *Prindsessen paa Ærten* (*The princess on the pea*) (Dal, 1963: 41–42) and a selection of translations of it into English illuminates the importance of recognizing intended repetitions in a source text. The source text of Andersen's story consists of 347 words, in which a form of the lexeme PRINDSESSE (PRINCESS) occurs 12 times. In the translations, this lexeme is typically re-presented using the lexeme PRINCESS. However, in the source text, PRINDSESSE is modified four times with the lexeme RIGTIG and three times with the lexeme VIRKELIG (VIRKELIG does not occur anywhere else in the story, whereas RIGTIG is also used also to modify the lexeme HISTORIE (STORY) in the last sentence). In a selection of translations of Andersen's text, his patterns of modification have not been re-presented; instead, the tendency is to vary more widely the adjectives used to modify the lexeme PRINCESS, and no adjective used to modify PRINCESS is also used to modify STORY. Therefore, readers of the translations tend not to face the questions raised by the patterns in the source text – about what characteristic the princess may share with a 'story' (in that they are both modified by RIGTIG) and whether Andersen uses the two near-synonyms, RIGTIG and VIRKELIG, interchangeably or to draw a qualitative distinction. Malmkjær argued that the source text patterns facilitate and support a reading of the story as a quest for a genuine (VIRKELIG) princess, as opposed to a woman who just looks like a stereotypical (RIGTIG) princess, by a prince who is uncertain about how to judge the princesses he meets on the genuineness-of-appearances parameter, and that this reading is further supported by a search for patterns of use of the same adjectives in Andersen's wider story opus. In fact, a broader search of Andersen's work shows a clear tendency to use RIGTIG to modify nouns standing for stereotypical examples of a kind, and to use VIRKELIG to modify nouns standing for the genuine article. Three text selections provide examples of this. Example (1) is from Andersen's *Nissen hos Spækhøkeren* (*The sprite at the charcuterie*) (1853):

(1) Der var en **rigtig** student, han
there was a **x** student he
boede paa Qvisten og
lived on attic-DEF and
ejede ingenting; der var en
owned nothing there was a
There was a . . . student, he lived in the
attic and owned nothing; there was a . . .
rigtig Spækhøker, han boede i
x charcuterier he lived in
stuen og eiede hele Huset.
ground and owned whole house-
floor-DEF DEF
. . . charcuterier, he lived on the ground floor and
owned the entire building.

Example (2) is from Andersen's *Svinedrengen* (*The swineboy*) (1842):

(2) 'Fy Papa!' sagde hun, 'den er
fie papa said she it is
ikke kunstig, den er **virkelig**!'
not artificial it is **x**
'Fie Papa!' she said, 'it is not artificial, it is . . . !'

Example (3) is from Andersen's *Nattergalen* (*The nightingale*) (1844):

(3) Den **virkelige** Nattergal sang paa
the **x** nightingale sang on
siin Maneer, og Kunstfuglen
its manner and artbird-DEF
gik paa Valser.
went on cylinders
The . . . nightingale sang in its own way, and
the artificial bird used cylinders.

Again, many translations do not reproduce such pattern of use, and Malmkjær (1994) argued that when trainee translators are helped to see the patterns in the original, compared with the lack of them in many translations, they will understand that an important dimension of the original story, along with an opportunity to arrive at a particular reading of it, may be lost to readers of the translation if the patterns of repetition are not re-presented in the translation (see also Malmkjær, 1995, 2003a).

Developing the Notion of Translational Stylistics

The early work in translational stylistics assumed unawareness on the part of translators, concerning certain patterns in the source texts. In later work, Malmkjær (2003b, 2004) defines translational stylistics as a text-focused search for answers to the question why, given a certain source text or set of source texts, a translation of the text (or of the set of texts) had been shaped by a translator in a particular way. This approach to translational stylistics assumes deliberate shaping of translations by translators to particular ends.

Emphasis on the source text distinguishes translational stylistics from approaches that concentrate on translators' styles as such, paying only secondary attention is given to the influence on their linguistic

choices exerted by aspects of the source text (see, for example, Baker, 2000). Emphasis on the source text also distinguishes translational stylistics from the interest expressed by Hermans (1996) in instances in which translators reveal themselves in their translations through paratextual material, such as translator's notes (Hermans, 1996: 27), or through textual choices that are likely to remind readers that they are reading a translation – for example, when character-motivated proper names in literature are translated literally into the language of the translation (e.g., in Dutch to English, Parson 'Wawalaar' becomes Parson 'Blatherer') (Hermans, 1996: 35), so that incongruity with the context is created: an obviously Dutch character bears an English name. Translational stylistics, however, does not distance itself from the wider aims of such approaches – in Baker's case, to point to the creative nature of translating (Baker, 2000: 262), and in Hermans's case, to incorporate into any model of translated narrative "the Translator as constantly coproducing the discourse" (Hermans, 1996: 43). Indeed, these aims are highlighted in studies in translational stylistics, which focus on translators' quests to minimize the potential to offend the religious and other sensibilities of an intended readership (Malmkjær, 2003b, 2004), or to contribute to the self-assertion of a nation (Millan-Varela, 1997a,b), or to reinterpret a classic for a new cultural context (Ben-Ari, 2002). If the arguments for such quests are supported by paratextual material such as that noted by Kovala (1996), so much the better; in fact, it is important that studies in translational stylistics draw on whatever historical, sociological, and biographical materials are available and relevant to the periods, places, languages, works, authors, and/or translators on which they concentrate.

The Argument for Translational Stylistics

Malmkjær (2004) suggests that studies in stylistics may be primarily oriented toward the text, the reader, or the writer, and that although studies oriented toward the text or toward the reader can be carried out on translations without regard to their source texts, writer-oriented stylistic studies of translations need to take account of relationships between translations and their sources:

> It is possible to analyse the style of any text, and it is possible to make claims about how any text elicits responses in the reading mind, irrespective of the text's manner of coming into being. In contrast, it is not possible through stylistic analysis of a translation alone to provide a satisfactory answer to the question *why* the translation has been made to mean as it does [Malmkjær, 2004: 16].

To find an answer to this question, it is necessary to take into consideration relationships that obtain between the translated text and its source; in fact, "unless this relationship is taken into consideration, many textual features of potential interest are unlikely to come to the notice of the analyst" (Malmkjær, 2004: 16). Consider the following extract from Henry William Dulcken's translation (1864) of Hans Christian Andersen's story, *Engelen* (*The angel*) (see Malmkjær, 2003b: 52–54):

> And the child opened his eyes and looked into the glorious happy face of the angel; and at the same moment they entered the regions where there is peace and joy. And the Father pressed the dead child to his bosom, and then it received wings like the angel, and flew hand in hand with him. And the Almighty pressed all the flowers to his heart, but he kissed the dry withered field flower, and it received a voice and sang with all the angels hovering around.

In the passage, an angel has come to collect a dead child together with the possession most dear to it while it lived, to take both to God. The possession is a field flower grown in a pot in the sick child's window, which brought the child happiness, but which was later discarded and left to wither. The passage recounts what happens next. There is nothing particularly remarkable about the passage; however, there are some remarkable relationships between it and its source, which reads as follows:

> Og Barnet aabnede ganske sine Øine og saae ind i Engelens deilige, glade Ansigt, og i samme Øieblik vare de i Guds Himmel, hvor der var Glæde og Lyksalighed. Og Gud trykkede det døde Barn til sit Hjerte, og da fik det Vinger som den anden Engel og fløi Haand i Haand med ham; og Gud trykkede alle Blomsterne til sit Hjerte, men den fattige, visne Markblomst kyssede han, og den fik Stemme og sang med alle Englene, der svævede om Gud [Hans Christian Andersen, *Engelen*].

If we set a gloss (G) of this source against Dulcken's translation (D), it becomes clear that the translation departs subtly from the original:

> G: And the child opened completely its eyes and looked into the angel's lovely
> D: And the child opened his eyes and looked into the glorious
>
> G: happy face, and at the same moment were they in God's heaven, where there
> D: happy face of the angel; and at the same moment they entered the regions where there
>
> G: was joy and bliss. And God pressed the dead child to his heart, and then
> D: is peace and joy. And the Father pressed the dead child to his bosom, and then

G: got it wings like the other angel and flew hand in hand with him; and God
D: it received wings like the angel, and flew hand in hand with him. And the Almighty

G: pressed all the flowers to his heart, but the poor, withered field flower kissed he,
D: pressed all the flowers to his heart, but he kissed the dry withered field flower,
G: and it got voice and sang with all the angels, that floated around God . . .
D: and it received a voice and sang with all the angels hovering around –

Where Andersen has a change of state from not being in Heaven to being in it, *og i samme Øieblik* ***vare*** *de i Guds Himmel* 'and at the same moment they **were** in God's heaven,' Dulcken has a change of position, an entering: 'and at the same moment they **entered** the regions where there is peace and joy.' In the source text, the change of state is simultaneous with the child opening its eyes **completely**. This is the third step in a process that begins earlier in the story when the child hears 'as if in a dream' the angel's story and continues when the angel kisses the child and 'the little one half opened its eyes.' Dulcken reproduces these two steps, but because he does not translate *ganske* 'completely,' the child's final, full vision of the angel is less clearly connected to the two previous stages on its path to 'visionariness,' the last stage coinciding with a metamorphosis of place. The translation presents an opening of the eyes that coincides with entering one region from another, separate region. Once in this region, Andersen's child has wings 'like the **other** angel,' suggesting that the child belongs to the same category of being as the angel; the angel in the translation remains unique: 'the angel.' In the source text, the child becomes winged and the flower becomes voiced. The Danish verb *at få*, although it can mean to be given something, can also mean to become the kind of person who has something, as in *Vi har fået hus* 'we have become house owners.' In contrast, Dulcken's child **receives** wings and the flower **receives** a voice. Dulcken's almighty is a benevolent God who bestows things, whereas Andersen's almighty is a transforming, overtly loving God.

Against the background of a wider study of Andersen's lexis, compared to Dulcken's, Malmkjær (2003b, 2004) links translation choices of this kind with a desire on the translator's part to create distance between the secular and the divine. In the passage quoted, there is a greater sense of physical distance between Heaven and Earth in the translation than there is in the source, because the translation has the characters entering from one sphere into another; there is greater metaphorical distance between the two spheres insofar as the child and the angel remain creatures of different types in the translation, and there is greater linguistic distance between the two regions insofar as the translation avoids naming the deity, using 'the regions where there is peace and joy' for 'God's heaven,' and using 'the Father,' 'the Almighty,' and '0' for 'God.' It is obvious that none of this would be so clearly noticeable in the translation alone as it is when the translation is compared with its source text. Dulcken's desire for distance is further linked to sociohistorical differences between attitudes to religion in Victorian Britain and in Andersen's Denmark.

Additional Examples of Studies in Translational Stylistics

Millán-Varela (1997b) shows how Otero Pedrayo used his translation (1926) into Galician of fragments of Joyce's *Ulysses* to promote Galician language and culture: "Otero the translator does not choose the expected literal translation which would have coincided in form both with the Latin forms of the ST and the Spanish language. Instead, he opts for an alternative solution: translate the meaning into 'pure' Galician forms" (Millán-Varela, 1997b: 288). For example, the purely Galician forms *xantar* 'diet' and *calzós* 'trousers' were chosen in preference to forms that Galician shares with Spanish, *dieta* and *pantalón*, even though the Galician choices carry with them nuances of meaning present in neither the source text nor in the potential Spanish/Galician equivalents: for example, *xantar* refers only to lunchtime and *calzós* makes reference to a traditional type of garment that used to be worn instead of trousers (Millán-Varela, 1997b: 288).

In a comparative study of eight translations into Hebrew of Lew Wallace's *Ben-Hur: a tale of the Christ* (1880), Ben-Ari (2002) shows how the translators respond to a long tradition of manipulating non-Jewish, especially Christian, material in translations into Hebrew (2002: 265):

> For generations, the existence of Christian elements in literary texts was regarded as problematic . . . and called for some kind of 'approach' or 'treatment', censoring the very translation of a text or interfering in various ways and degrees in the straightforwardness of operational stages of the translation.
>
> The reasons are so manifold it would be presumptuous to attempt to analyze them within the framework of translation norms, unless the larger context of the Judaism–Christianity dichotomy into account. More than in any other discussion of norms, the intertwined elements at work here exemplify the complexity of the issues involved in cultural interference and cultural research.

Ben-Ari shows how, in the translations into Hebrew, Ben-Hur who in the original text begins life as a Jew

but converts to Christianity, is converted back to the Jewish faith, and how the novel's model of Christianity is converted into a 'Jews against Romans' model (Ben-Ari, 2002: 272). This is done partly by the elimination or alteration of Christian elements – very obviously, for example, in the conversion of the subtitle, *A tale of the Christ*, into *Sipur histori mi-yme ha-bayit ha-sheni* 'A historical tale from the period of the Second Temple' (Ben-Ari, 2002: 277), and in the omission, from all but two translations, of Book First of the original, which deals with the birth of Christ (2002: 283). Smaller scale linguistic filters include, for example, the omission of the name of the village of Nazareth, which becomes 'a village in Galilee' (2002: 287), and the provision of chapter headings instead of the original text's numbering system. Ben-Ari (2002: 292) specifically mentions the chapter heading, 'A Jew and a Roman'.

Elisabeth Closs Traugott is a Professor Emeritus of Linguistics and English at Stanford University in California. She began her undergraduate studies at Oxford University in 1957 and completed her graduate studies at the English department of the University of California at Berkeley in 1964. She held an assistant professorship in the Department of English at Berkeley from 1964 to 1970. In 1970 she became an Associate Professor of Linguistics and English at Stanford and has held full professorship at the same school since 1977. Traugott has also been a Fellow at the Center for Advanced Study in the Behavioral Sciences, and a Guggenheim Fellow.

Traugott has conducted research on historical syntax and semantics, sociohistorical linguistics, and linguistics and literature. Her first major publication is *A history of English syntax: a transformational approach to the history of English sentence structure* (1972). This book analyzes the fundamental constructions and events of English historical syntax (changes in the verbal system, in surface case forms, in dominant word order types, in negative and interrogative sentence patterns, in complementation and relativization, among others). Traugott also examines several instances of foreign (French, Latin, Old Norse) influence on English syntax. This work

but converts to Christianity, is converted back to the Jewish faith, and how the novel's model of Christianity is converted into a 'Jews against Romans' model (Ben-Ari, 2002: 272). This is done partly by the elimination or alteration of Christian elements – very obviously, for example, in the conversion of the subtitle, *A tale of the Christ*, into *Sipur histori mi-yme ha-bayit ha-sheni* 'A historical tale from the period of the Second Temple' (Ben-Ari, 2002: 277), and in the omission, from all but two translations, of Book First of the original, which deals with the birth of Christ (2002: 283). Traugott, Elizabeth

S-H Seong, University of Bonn, Bonn, Germany

© 2006 Elsevier Ltd. All rights reserved.

Elisabeth Closs Traugott is a Professor Emeritus of Linguistics and English at Stanford University in California. She began her undergraduate studies at Oxford University in 1957 and completed her graduate studies at the English department of the University of California at Berkeley in 1964. She held an assistant professorship in the Department of English at Berkeley from 1964 to 1970. In 1970 she became an Associate Professor of Linguistics and English at Stanford and has held full professorship at the same school since 1977. Traugott has also been a Fellow at the Center for Advanced Study in the Behavioral Sciences, and a Guggenheim Fellow.

Traugott has conducted research on historical syntax and semantics, sociohistorical linguistics, and linguistics and literature. Her first major publication is *A history of English syntax: a transformational approach to the history of English sentence structure* (1972). This book analyzes the fundamental constructions and events of English historical syntax (changes in the verbal system, in surface case forms, in dominant word order types, in negative and interrogative sentence patterns, in complementation and relativization, among others). Traugott also examines several instances of foreign (French, Latin, Old Norse) influence on English syntax. This work

excellently summarizes the research tradition in the field of historical syntax. The chapters include Modern English syntax, Old English, Middle and Early Modern English, and Modern English since 1700. While this research manifests a Chomskyan influence, it is also supplemented by performative analysis and case grammar.

Her other research contributions focus on language change, particularly grammaticalization, lexicalization of conversational inferences, and subjectification; clause combining, particularly conditionals, concessives, and causal clauses. Some of her important articles in these areas include '*And* and *But* connectives in English' (*Studies in language*, 1986), 'On the rise of epistemic meanings in English: an example of subjectification in semantic change' (*Language*, 1989). With respect to clause combining, the investigation of the historical paths of English connectives *and* and *but* shows that there is a strong tendency for spatial and temporal meanings to give rise to logical connective meanings. In regard to the subjectification process in semantic change, it is demonstrated that "meanings tend to become increasingly situated in the speaker's subjective belief state or attitude towards the proposition." The semantic changes of modal auxiliaries (e.g., *must*), assertive speech act verbs, and modal adverbs show that epistemics develop from more root, deontic, and concrete meanings to more strongly subject epistemicity.

Her seminal book *Grammaticalization* (1993; 2nd edn. 2003, with P. Hopper) deals with historical as well as synchronic linguistics whereby "lexical items and constructions come in certain linguistic contents to serve grammatical functions, and, once grammaticalized, continue to develop new grammatical functions" (2003: xv). This change corresponds to the shift of content words to pure function words.

Traugott also co-authored *Regularity in semantic change* with R. Dasher (2001) in which cross-linguistic unidirectional tendencies in semantic change are discussed in detail. Her writings also include *Linguistics for Students of literature* (1980; with M. L. Pratt), and *On conditionals* (1986; co-edited).

Introduction

Treebanks, by definition, are series of trees that arise from parsing a textual form of a sentence (as it appears on a printed page or in an electronic article, or that is a transcribed spoken utterance). Parsing of a sentence is an intermediate step on the way from a surface expression (written or spoken) to a formal sentence understanding representation. It is believed that parsing is a crucial step on that way, being the first one (after tokenization or acoustic processing, phonological, morphological, and other 'low-level' procedures) that assigns a structure to the analyzed utterance. Treebanks thus capture the result of such parsing of many utterances (typically, a continuous series of sentences and documents originally collected in an electronic corpus).

Treebanks are created (annotated) manually, by linguists (or by non-linguists with some linguistic training and under supervision by linguists), who also prepare and gradually refine the treebank annotation guidelines. The typical size of a treebank is hundreds of thousands to one or two million word tokens (tens to hundreds of thousands of utterances).

The purpose of treebanks is essentially twofold. First, they serve as an exact, explicit formal description of language structure under a given theory or formalism for further linguistic research (whether structural, lexical, or any other). Second, they can be used for automatic training of parsers – by machine learning, probabilistic, statistical, or other data-driven algorithms to derive features, rules, or other formal mechanisms (possibly with probabilities, weights, or scores) that can be then used to automatically replicate on some other, previously unseen data, the process of parsing that leads to the original treebank. Using such a trained parser, a much larger

Introduction

Treebanks, by definition, are series of trees that arise from parsing a textual form of a sentence (as it appears on a printed page or in an electronic article, or that is a transcribed spoken utterance). Parsing of a sentence is an intermediate step on the way from a surface expression (written or spoken) to a formal sentence understanding representation. It is believed that parsing is a crucial step on that way, being the first one (after tokenization or acoustic processing, phonological, morphological, and other 'low-level' procedures) that assigns a structure to the analyzed utterance. Treebanks thus capture the result of such parsing of many utterances (typically, a continuous series of sentences and documents originally collected in an electronic corpus).

Treebanks are created (annotated) manually, by linguists (or by non-linguists with some linguistic training and under supervision by linguists), who also prepare and gradually refine the treebank annotation guidelines. The typical size of a treebank is hundreds of thousands to one or two million word tokens (tens to hundreds of thousands of utterances).

The purpose of treebanks is essentially twofold. First, they serve as an exact, explicit formal description of language structure under a given theory or formalism for further linguistic research (whether structural, lexical, or any other). Second, they can be used for automatic training of parsers – by machine learning, probabilistic, statistical, or other data-driven algorithms to derive features, rules, or other formal mechanisms (possibly with probabilities, weights, or scores) that can be then used to automatically replicate on some other, previously unseen data, the process of parsing that leads to the original treebank. Using such a trained parser, a much larger

treebank can be constructed automatically, even though only the best automatic parsers achieve less than 10% errors (for a discussion of error rate, see the section 'Using Treebanks: Searching and Parsing' in this article). Although automatically parsed treebanks can serve well for linguistic research that can tolerate the parsing output noise, they cannot be relied upon by further automatic processing as can the original, manually annotated treebanks, and they can be used (with caution) only for certain specific purposes.

Manual treebank annotation is a lengthy, expensive process (both in terms of human resources and actual money spent during the process). It is expected that treebanks will be reused for many projects for both of the aforementioned purposes; they are typically published for worldwide distribution by one of the leading publishers of electronic language resources, the Linguistic Data Consortium (Philadelphia, PA, USA) or ELRA/ELDA (Paris, France).

Types of Treebanks

Known treebanks can be classified into two groups according to the underlying view of the linguistic theory used:

- parse-tree (constituent, phrase-structure) treebanks, and
- dependency treebanks

Parse-tree treebanks can be almost, without change, viewed as derivation trees of some context-free grammar (CFG), with the original theory of phrase-structure grammars (PSG) being closest in its formulation. Dependency treebanks are typically close to the functional view, such as the Functional Generative Description Theory or the Meaning-Text Theory.

Parse-Tree Treebanks

A context-free grammar backbone is behind all such treebanks. Each node has in principle only a single label. The root of the tree (typically denoted S, for 'Sentence', or 'Start symbol' in CFG terminology) is typically split to two or more subtrees with other phrase labels (such as NP for noun phrase, VP for verb phrase, etc.; these are called non-terminal symbols in CFG terminology). Recursively, the subtrees are split further and further, until a terminal node (a node with no descendants) is reached; the terminal nodes correspond to the surface form of words in the analyzed sentence. The nodes just above the terminal nodes are called pre-terminals; they are labeled not by phrase labels, but by the POS (part-of-speech) tags assigned to the words at the terminal nodes below them. The number of nodes in a parse-tree treebank (if pre-terminal nodes are used) is thus between twice and three times the number of tokens in the analyzed sentence, or even more if some non-branching non-terminals are employed in the tree. An example of a tagset used for a parse-tree treebank follows.

```
(S (NP Industrial production)
   (VP increased
       (PP by
           (NP 0.8 percent))
       (PP in
           (NP December))))
```

Figure 1 Example parse tree with phrase labels *(Industrial production increased by 0.8 percent in December).*

S (Sentence)
NP (Noun Phrase)
VP (Verb Phrase)
AUXV (Auxiliary Verb)
ADJP (Adjectival Phrase)
ADVP (Adverbial Phrase)
PP (Prepositional Phrase)
SBAR (Relative Clause, Subordinate Clause)
FRAG (Fragment)
PRN (Parenthetical)
CONJP (Multi-word Conjunction)
UCP (Unlike Coordinated Phrase)

Figure 1 shows an example of an annotated parse-tree.

Dependency Treebanks

In dependency treebanks, no non-terminal or phrase-marking labels are used. Instead, nodes in the dependency tree are labeled by complex labels (attribute-value pairs). There are at least three of them at each node: the word (in its surface form) itself, its POS tag, and some sort of a functional label. The edges of the tree denote dependency: from the root to the leaves, the 'upper' node of an edge is called the 'governor' and the lower one is called the 'dependent.' Even though the direction of the dependency is sometimes theory-dependent, verbs typically govern its complementations (arguments and adjunct), nouns their attributes and other modifiers, conjunctions the subordinate clauses they precede, prepositions the head noun of the phrase they belong to, etc. The number of nodes in a dependency treebank is thus equal to the number of tokens in the analyzed sentence.

A possible list of dependency functional labels in such a treebank follows.

Pred (Predicate)
Sb (Subject)
Obj (Object)

Figure 2 Example surface-syntactic dependency tree *(Industrial production increased by 0.8 percent in December).*

Adv (Adverbial (all types))
Pnom (Nominal part of a predicate)
Atr (Attribute)
AuxV (Auxiliary verb (to_be))
AuxP (Preposition)
AuxC (Subordinate conjunction)
AuxZ (Intensifier)
AuxG (Graphical symbol)
AuxR (Reflexive particle)
Coord (Coordination)

Figure 2 shows their usage in a partially annotated syntactic dependency tree.

Type Difference

Treebank types are, after all, not as different as they might seem from their description. Parse-tree treebanks can be converted into dependency treebanks if heads (governing nodes in the resulting converted dependency tree) are determined for every non-terminal in the corpus, which might be a very non-trivial task if they are not manually annotated. Dependency treebanks can be converted into parse-tree treebanks under two basic conditions: first, a strategy has to be determined for whether the resulting trees should be primarily deep or wide (or something in between, based on the language, style of annotation, purpose of conversion, etc.), and second, a procedure for naming the newly created non-terminal nodes must be devised that can use only the existing dependency type labels. Moreover, if the dependency trees are not projective, additional considerations must be taken into account.

While the parse-tree style of annotation can be (almost) directly used for training automatic parsers, the dependency trees are believed to have the advantage of being closer to semantic interpretation of the sentence and therefore more suitable for further (deeper) analysis.

The Complexity and Depth of Annotation: From Syntax to Semantics and Beyond

The basic types of treebanks already described are also referred to as (surface) 'syntactic treebanks.' Various schemes have been designed to 'deepen' the annotation towards a (syntactico-)semantic, pragmatic, content or 'logical' annotation. For example, the predicate-argument structure of verbal or nominal clauses is annotated (similarly in treebanks based on other theories, valency structure of verbs and some nouns and adjectives can be annotated), function words (and/or inflection for languages that use it extensively) can be generalized and formalized into a detailed set of node function labels, and various grammatical functions can be reflected in an enriched set of node labels. More structure that complements the basic tree structure of the sentence analysis representation is introduced for anaphora links (and co-reference in general), and the information and discourse structure of the sentence is annotated as well. These various schemes always contain links back to the basic syntactic annotation or are directly embedded in it in order to facilitate automatic learning of the process of 'deepening' the sentence analysis (and vice versa). Examples of functional (dependency) labels follow.

PRED (Predicate)
ACT (Actor)
PAT (Patient (2nd verbal argument))
ADDR (Addressee)
EFF (Effect)
BEN (Benefactor)
LOC (Location)
TWHEN (Time-when)
THO (Time-how often)
AIM (Aim)
CAUS (Cause)
RSTR (Restrictive Attribute)
DIFF (Difference)
DISJ (Disjunctive coordination)
RHEM (Rhematizer)

Figure 3 shows an example of a deep syntactico-semantic annotation.

Lexicons and Treebanks

Treebanks are sometimes accompanied by lexicons that contain the context-independent information about lexical behavior of words at the given level of annotation. For inflectionally rich or agglutinative languages, a morphological dictionary is often provided that lists many more words than can be found in the annotated treebank, facilitating processing of

Figure 3 Example deep syntactic (functional) sentence representation *(Industrial production increased by 0.8 percent in December).*

general texts. For deeply (semantically) annotated corpora, a 'valency' lexicon or a 'PropBank' lexicon (both essentially listing possible arguments of words of various parts of speech, in a theory/annotation dependent way) accompany such a corpus, often with links between the lexicon entry occurrences in the corpus and the lexicon entries themselves, for easy reference.

Parallel Treebanks

For multilingual applications, most notably for machine translation, parallel treebanks provide an advantage to ordinary parallel corpora in that they can be used for inducing reliable structural correspondence between the languages in question. It is believed that structural differences between languages, especially at the semantic level, are much smaller than the differences observed at the word level (such as different word order, use of function words vs. inflection in the other language, etc.). Very few parallel treebanks exist today, but some are under construction.

The Process of Treebank Annotation

Manual annotation of a million-word (or bigger) treebank is a complex task that includes several stages and a varying size of the annotation team. The annotation guidelines have to be written first (even though they are necessarily being modified and extended during the process). Data has to be selected and technologically prepared for annotation, and annotation software has to be acquired or created. Decisions have to be made about how much automatic pre-annotation is desirable given the main goals of the annotation project and the time and budget constraints; one has to be cautious here because the team members may be influenced by the pre-annotation. Annotators have to be chosen and trained, and their ability to follow the guidelines, work effectively, and focus for many hours (which is often unrelated to their education or age) has to be assessed before the final selection is made.

During the process of annotation, inter-annotator agreement has to be measured and problems must be solved quickly by modifying the guidelines and/or retraining the annotators. Software has to be maintained and enhanced during the process of annotation to make the process more efficient and less error-prone. If the teams of annotators are specialized (to annotate only a subset of the node labels, for example) and work in parallel on the same data, extreme care has to be taken when merging the annotation into a single final corpus. Access to dictionaries and the annotated corpus (if the annotation is performed onsite and/or online, with direct access to the actual data) must be controlled in order to avoid simultaneous changes, much as in large online databases. When the annotation is finished, it has to be extensively checked at various levels (low-level markup, consistency with the final version of the guidelines, consistency between the groups of annotators; consistency inside the data, if possible; link targets for additional superimposed structure; etc.).

Last, the result must be prepared for publication with full documentation, examples of use, viewing and processing software for general use, pointers to papers and articles about the underlying theory, current use, or other aspects of annotation, pointers to similar or complementary projects, etc.

Typically, the annotation itself as performed by the annotators forms only 15 to 30% of the total effort. The cost of producing a syntactic treebank of a reasonable size is about $1 per annotated word, and can triple (or worse) if some form of a complex, 'deep' semantic annotation is used.

Existing Treebanks: a Short Survey

The first and most used treebank of all time is the Penn Treebank (Marcus *et al.*, 1993). It is of the parse-tree type and contains 1.3 million annotated words (English articles from the Wall Street Journal from the end of the 1980s and beginning of the 1990s.) The treebank has been enhanced since its first publication (e.g., the set of non-terminal labels has been extended to contain functional information as well). Recently, predicate-argument annotation has been superimposed on the Penn Treebank, based on the PropBank (Kingsbury and Palmer, 2002) and NomBank (Meyers *et al.*, 2004) projects.

The Czech-language Prague Dependency Treebank project (Hajič *et al.*, 2001) uses the dependency-type of annotation (based on the Functional Generative Description theory (Sgall *et al.*, 1986)), and consists of two treebanks whose nodes are linked together:

one contains the annotation of the morphological and surface syntactic structure of Czech, and the other one (on the same data) contains the 'deep' complex annotation of valency, detailed dependency and grammatical functions (a total of 16 node labels), co-reference, and information structure of the sentence.

The German TIGER (Brants *et al.*, 2002) corpus (an extension of an earlier and smaller Negra corpus) contains a mixture of both types of annotation (parse-tree and functional/dependency). On top of the usual non-terminals used for denoting the underlying parse-trees, a wide-coverage LFG grammar formalism has been used for the functional style of annotation. Verb subcategorization is also used as part of the annotation. The corpus has been prepared semi-automatically; however, this corpus is considered a manually annotated one because of the amount of manual work and checking that went into its creation.

There are other treebanks being used and/or created, such as for the Arabic, Bulgarian, Chinese, Danish, Dutch, Hungarian, Italian, Slovak, Slovenian, Swedish, Turkish, and other languages. These treebanks are typically smaller in size, and they are modeled after one of the basic types; sometimes (for example, the Arabic one) they are using (almost) the same sets of labels as the Penn or the Prague Dependency Treebanks. The largest spoken language treebank is the English Switchboard corpus (Godfrey *et al.*, 1992); however, it has been parsed automatically (not manually) by one of the statistical parsers trained on the Penn Treebank.

Using Treebanks: Searching and Parsing

Linguists are interested in searching treebanks, which is a much more complex task than searching an ordinary (linearly ordered) corpus, both from a mathematical and an end-user point of view. Instead of – or in addition to – formulating corpus queries in terms of distance between words, syntactic relations are the core of the queries. For example, one might search for all clauses in which two direct objects are used, regardless of the verb that heads such a phrase. In the case of deeper annotation, one might formulate even more complex queries, such as finding all instances of personal pronouns that refer outside a clause boundary (and perhaps to express their count as the percentage of all personal pronouns used in the corpus). Currently, very few general-purpose tree search systems exist. A rudimentary search system is called `tgrep`, a tree search system operating on principles similar to those of the file-searching `grep` utility (and suitable especially for the Penn Treebank), but without a graphical user interface. TIGERSearch, a tool to search corpora following the TIGER treebank style of annotation, does contain such an interface, as does the Netgraph system that accompanies some of the treebanks published by the Linguistic Data Consortium. Other systems are currently being developed, usually to accompany treebanks developed by various research groups.

The Computational Linguistics community sees the main purpose of treebanks in automatically training parsers. The manually annotated data is fed into a system that automatically derives features or rules and/or their weights or probabilities from the manual annotation and stores them as a parsing 'model'. Once trained, such parsing model used with appropriate parsing software can automatically replicate the manual annotation on new texts and thus be eventually made part of natural language processing applications. Good parsers, however, do not have to necessarily be trained automatically (before the advent of treebanks, it was not even possible to do so). The logical question then arises when comparing parsers of any kind – which of them is better? Again, treebanks provide the answer: parser output can be compared to the manually annotated data (obviously, it is different than that used for training a data-driven parser) and numerically evaluated. The error function used depends on the type of treebank. In the case of parse-tree treebanks, the measure concerns the number of 'crossing brackets (and their labels)', i.e., roughly speaking, the number of subtrees whose spans do not match that of the manually annotated sentence. For dependency treebanks, the measure is even simpler – every node that is not correctly attached to its 'true' (i.e., manually annotated) governor, or has the wrong label, counts as an error.

Summary

Treebanks, since the publication of the first one, the Penn Treebank, have been the source of a true revolution in Computational Linguistics, especially in the area of parsing natural language sentences. With limited research resources and the apparent high cost of building treebanks, we cannot currently hope for substantially larger manually annotated treebanks – despite the desperate need for them; further research is needed to discover ways of annotating more textual and spoken data with the reliability attainable by humans but using much more efficient methods.

Jost Trier, the son of a medical doctor, was born in Schlitz. He studied German and Roman languages as well as comparative linguistics in Freiburg, Basel, Berlin, and Marburg. He received a professorship in German philology in 1932 at the *Westfälische Wilhelms-Universität*, Münster, where he became *Rektor* in 1956–1957 and *Prorektor* the following year. He became a member of the *Akademie der Wissenschaften* in Göttingen (1939) and was made *Ehrenmitglied* of the *Deutscher Germanistenverband* (1962) and of the *Institut für Deutsche Sprache* (1969). He was awarded the Konrad-Duden Prize (city of Mannheim, 1968), for having honored the German language with his work. Trier died in Bad Salzuflen in 1970, and his letters, manuscripts, and personal documents are stored at the University of Münster.

Trier, inspired by Saussure and influenced by Humboldt, developed, after Weisgerber's research, the lexical field method as applied to German etymology. His work *Der deutsche Wortschatz im Sinnbezirk des Verstandes. Die Geschichte eines sprachlichen Feldes* (1931), was the foundation for research in field semantics. He was an innovator in adopting a structuralist approach to studies of word meaning. He used each lexical item according to its semantic relations with the other items, to consider individual words and to group into lexical fields. As his interest was studying the whole system more than individual words, such an analysis was meant to cover the whole vocabulary: based on this, Trier chose small conceptual areas of vocabulary for his 'mosaic model'; for instance, the abstract notions of 'knowledge' in medieval German – *wîsheit*, *kunst,* and *list* – the former being a superordinate, the latter ones hyponyms, and, by the end of the 13th century, the structure of the field changed; *wîsheit* was no longer a generic, *list* had left the group, and *wizzen* had entered it.

The semantic field analysis shows that a conceptual region may change according to different languages or to successive states of a language. Trier's theory was criticized for considering vocabulary as a single

Trier, Jost (1894–1970)

D Candel, CNRS, University of Paris 7, Paris, France

© 2006 Elsevier Ltd. All rights reserved.

Jost Trier, the son of a medical doctor, was born in Schlitz. He studied German and Roman languages as well as comparative linguistics in Freiburg, Basel, Berlin, and Marburg. He received a professorship in German philology in 1932 at the *Westfälische Wilhelms-Universität*, Münster, where he became *Rektor* in 1956–1957 and *Prorektor* the following year. He became a member of the *Akademie der Wissenschaften* in Göttingen (1939) and was made *Ehrenmitglied* of the *Deutscher Germanistenverband* (1962) and of the *Institut für Deutsche Sprache* (1969). He was awarded the Konrad-Duden Prize (city of Mannheim, 1968), for having honored the German language with his work. Trier died in Bad Salzuflen in 1970, and his letters, manuscripts, and personal documents are stored at the University of Münster.

Trier, inspired by Saussure and influenced by Humboldt, developed, after Weisgerber's research, the lexical field method as applied to German etymology. His work *Der deutsche Wortschatz im Sinnbezirk des Verstandes. Die Geschichte eines sprachlichen Feldes* (1931), was the foundation for research in field semantics. He was an innovator in adopting a structuralist approach to studies of word meaning. He used each lexical item according to its semantic relations with the other items, to consider individual words and to group into lexical fields. As his interest was studying the whole system more than individual words, such an analysis was meant to cover the whole vocabulary: based on this, Trier chose small conceptual areas of vocabulary for his 'mosaic model'; for instance, the abstract notions of 'knowledge' in medieval German – *wîsheit*, *kunst,* and *list* – the former being a superordinate, the latter ones hyponyms, and, by the end of the 13th century, the structure of the field changed; *wîsheit* was no longer a generic, *list* had left the group, and *wizzen* had entered it.

The semantic field analysis shows that a conceptual region may change according to different languages or to successive states of a language. Trier's theory was criticized for considering vocabulary as a single

global field or for taking into account only paradigmatic relations. Late with respect to the other language sciences, semantics branched into field semantics as advocated by Trier and developed only after World War II, as functional and structural semantics (in particular with Ullmann, Guiraud, Greimas). Componential analysis is now seen as a consequence of the theory of semantic fields. A source of semantic change studies – field theory – also developed into sociolinguistics and variationism.

Trinidad and Tobago: Language Situation

V Youssef, The University of the West Indies, St Augustine, Trinidad and Tobago

© 2006 Elsevier Ltd. All rights reserved.

Geographical Location

Trinidad and Tobago is the most southerly nation in the Eastern Caribbean region, lying immediately north of the South American continent, near Venezuela.

Historical Overview: Language Shift and Development

As a twin island state it arguably represents a single speech community, although its language history and present linguistic status remain partially distinct. Although Trinidad went through periods of Spanish (1498–1797) and English rule (1802–1963), the French had a powerful influence because they were encouraged to settle the island by the Spanish from 1783. Additionally, the island was inhabited from the mid-19th century by indentured laborers from India, who came between 1849 and 1917; the Indian language that won out among them was Bhojpuri (cf. Mohan and Zador, 1986), a language variety of northwest India that is only today disappearing as a native language. During the 19th century 2500 Chinese (1853–1886), some Syrians and Lebanese, and 1298 Portuguese speakers from Madeira (Ferreira, 1994, 1999), all came to Trinidad, as well as freed slaves. Tobago had a more exclusively English influence despite many European skirmishes.

In both territories creole languages were established immediately following the importation of large numbers of African slaves. In Trinidad, slaves came mainly from other parts of the Caribbean, whereas in Tobago more came directly from Africa, as well as from elsewhere in the Caribbean. In Tobago, the plantation continued to be the focal point of people's lives, after emancipation in 1838, whereas in Trinidad, Afro-Trinidadians moved to the towns, and the plantations had to be worked by indentured laborers.

There are lexical influences (cf. Allsopp, 1996) from all the languages mentioned, as well as from the original Amerindian languages, both Carib and Arawakan, whom the Spanish decimated (cf. Baksh-Soodeen, 1995). Throughout the 19th century linguistic duality is attested between French and English-lexicon creoles: people gradually became bilingual in French and English creoles but hid the latter, feigning incomprehension of their ruling class (cf. Winer, 1984). A basilectal French creole is attested for Trinidad but there appears to have been no basilectal English creole therein; rather, there was a crossover from French-lexicon basilect to English-lexicon mesolect, which spanned a transition period from the late 19th to the early 20th centuries. There are influences from the French creole still present in modern Trinidadian speech.

Tobago, however, has retained an English-lexicon basilect down to the present. Not only did it have a more consistently British history, but it also retained a rural economy, based on agriculture and a village-based social life, such that the oldest variety of language was retained intact. Old people in Tobago tend to regard the mesolect as a Trinidadian intrusion and a corrupt mixed language variety, whereas for the younger generation, the mesolect has become their chief variety of identification. Increased contact with

Geographical Location

Trinidad and Tobago is the most southerly nation in the Eastern Caribbean region, lying immediately north of the South American continent, near Venezuela.

Historical Overview: Language Shift and Development

As a twin island state it arguably represents a single speech community, although its language history and present linguistic status remain partially distinct. Although Trinidad went through periods of Spanish (1498–1797) and English rule (1802–1963), the French had a powerful influence because they were encouraged to settle the island by the Spanish from 1783. Additionally, the island was inhabited from the mid-19th century by indentured laborers from India, who came between 1849 and 1917; the Indian language that won out among them was Bhojpuri (cf. Mohan and Zador, 1986), a language variety of northwest India that is only today disappearing as a native language. During the 19th century 2500 Chinese (1853–1886), some Syrians and Lebanese, and 1298 Portuguese speakers from Madeira (Ferreira, 1994, 1999), all came to Trinidad, as well as freed slaves. Tobago had a more exclusively English influence despite many European skirmishes.

In both territories creole languages were established immediately following the importation of large numbers of African slaves. In Trinidad, slaves came mainly from other parts of the Caribbean, whereas in Tobago more came directly from Africa, as well as from elsewhere in the Caribbean. In Tobago, the plantation continued to be the focal point of people's lives, after emancipation in 1838, whereas in Trinidad, Afro-Trinidadians moved to the towns, and the plantations had to be worked by indentured laborers.

There are lexical influences (cf. Allsopp, 1996) from all the languages mentioned, as well as from the original Amerindian languages, both Carib and Arawakan, whom the Spanish decimated (cf. Baksh-Soodeen, 1995). Throughout the 19th century linguistic duality is attested between French and English-lexicon creoles: people gradually became bilingual in French and English creoles but hid the latter, feigning incomprehension of their ruling class (cf. Winer, 1984). A basilectal French creole is attested for Trinidad but there appears to have been no basilectal English creole therein; rather, there was a crossover from French-lexicon basilect to English-lexicon mesolect, which spanned a transition period from the late 19th to the early 20th centuries. There are influences from the French creole still present in modern Trinidadian speech.

Tobago, however, has retained an English-lexicon basilect down to the present. Not only did it have a more consistently British history, but it also retained a rural economy, based on agriculture and a village-based social life, such that the oldest variety of language was retained intact. Old people in Tobago tend to regard the mesolect as a Trinidadian intrusion and a corrupt mixed language variety, whereas for the younger generation, the mesolect has become their chief variety of identification. Increased contact with

Trinidad helped to spread the variety, but it also developed within Tobago, as the education system encompassed more and more of the 20th-century population.

Present-Day Language Situation

The Language Complex

Today, the Standard and the mesolectal Creole variety are shared by the two islands, but the basilect is exclusive to Tobago. When collecting data in the 1990s we found that the basilect is still being acquired by some young rural-based Tobagonians as their first home variety (James and Youssef, 2002). Each language variety has its own social-psychological value such that a necessary continuous shift away from the Creole and toward Standard is not envisaged, but is a potential stabilization of the contact varieties. Although the Creole is the language of humor, solidarity, emotion, and national identification, the standard is the language of education, government, and the professions. The recognition of the Creole as a language in its own right in 1975, has led to the mesolect's much wider usage in all spheres, however, and ordered code-mixing has become normative in many contexts including the classroom.

The language varieties of Trinidad have been described from a sociolinguistic perspective by Winford (1972) and with concern for the rootedness of Trinidadian in the French Creole past by Solomon (1993). The language varieties of Tobago have been recently described (James and Youssef, 2002), since it was recognized that the two islands have been lumped together as one without concern for the separate language status of Tobago. The language acquisition duality has been investigated (Youssef, 1990), and Youssef (1996) explicates the communicative competence of adult speakers. Descriptions of the grammatical and phonological systems of the twin-island state are shortly to appear (James and Youssef, 2004; Youssef and James, 2003).

As an exemplifying subset, the verb system has three types of structure: main verb structure (e.g., *She eat she food*), copula structure (e.g., *She de a yard*), and copula-less structures (e.g., *She sick*) within which adjectives in the English system function as verbs in the creole one. All three subsystems are modified by preverbal tense, aspect, and mood (TAM) markers and a single aspect suffix *-in(g)*. These markers exhibit consistent discourse functions, denoting background or foreground focus, and different kinds of mood (For further detail see Chapter 5 of James and Youssef, 2003).

In a recent analysis of Caribbean Creole markers and their labels, Youssef (2002) synthesized past analyses (e.g., Bickerton, 1975; Solomon, 1993; Winford, 1993) of the oppositional systems of labeling, deducing a comprehensive perfective label in the zero marker, ranged in opposition to imperfective marking in *bin, bina* and *a* (basilectal) and in *did, was + -in* and *-in* (mesolectal). There is no fit with the English tense-aspect-modality system for any single marker, and this situation makes acquisition of the latter problematic for creole speakers who assume synonymity of systems.

Speaker Range and Competence

Speakers in both islands command, either wholly or partially, two or three language varieties, which they use separately or mix systematically. Code mixing is the unmarked norm, and individuals cannot readily 'unmix' in some cases. Children vary their speech stylistically from the very start of language acquisition, and three-year-olds balance among their codes according to situation, setting, and addressee. The term varilingualism was coined to describe this overall competence (Youssef, 1990, 1991, 1996), because the capacity to mix varieties is built into the development of grammatical competence from the earliest stage. The situation is not unlike that of some Hispanic speakers growing up in the United States where English and Spanish are mixed in some contexts (cf. Field, 1994; Zentella, 1997), but censure is less locally, due to the common Anglophone lexical base.

Current Influences and Cultural Forms: A Multicultural Entity

Today there are strong influences on local language from both the United States and Jamaica, sources of cultural influence through the media. Large diasporic communities of Trinbagonians can be found in New York, Miami, and London, where they integrate and adopt local accents more readily than Jamaicans, Barbadians, and others. This matter of language identity in the diaspora awaits critical research, however.

Internally Trinidad and Tobago has indigenously evolved cultural forms including chutney, an Indian calypso-influenced song and dance form, as well as the more well known calypso, institutionalized especially in Carnival, a complex and brilliant visual and musical arts extravaganza. Steel band music is an integral part of this celebration as well as independently having won world acclaim. Art forms are mentioned because there is a continuity between the linguistic and cultural diversities of the Trinbagonian people as expressive outworkings of a multicultural entity, unrivaled elsewhere in the Caribbean. The various musical forms may all be accessed via the website Fetenet.com, which simultaneously exposes

interested readers to the language of the territory described.

Trnka, Bohumil (1895–1984)

J Rischel, Mahidol University, Thailand

© 2006 Elsevier Ltd. All rights reserved.

Bohumil Trnka was born near the Czechoslovakian town Humpolec on June 3, 1895. He died in Prague in 1984. At an early age he established himself as an authority on the English language and he remained in that field throughout his scholarly career, from 1925 as Professor of English language and older English literature at Charles University, Prague, followed by two decades of active retirement in which he was a well-known figure in European linguistics.

Among Trnka's major works within the field of English studies are a monograph on the historical syntax of the English verb (Trnka, 1930) and another monograph on Modern English phonology (Trnka, 1935). The latter work was a pioneering accomplishment; it was in fact the first such treatise to appear, and it was followed by other such prewar works within the Praguean trend (e.g., a monograph on Danish phonology by André Martinet, 1937).

In his breadth of study in the field of English studies and general linguistics Trnka was rather reminiscent of Otto Jespersen. Throughout his active scholarly life Trnka published on a wide variety of subjects within descriptive English grammar and phonology, notably on word classes and on word formation (an area in which Jespersen had not arrived at a fully satisfactory approach). Trnka developed a theory of word classes in English according to which nouns and verbs were constituted morphologically – by the inflectional categories associated with them. In his last work (Trnka, 1990) he delved into the relationship between language and society, like Jespersen and Sommerfelt before him.

Trnka, Bohumil (1895–1984)

J Rischel, Mahidol University, Thailand

© 2006 Elsevier Ltd. All rights reserved.

Bohumil Trnka was born near the Czechoslovakian town Humpolec on June 3, 1895. He died in Prague in 1984. At an early age he established himself as an authority on the English language and he remained in that field throughout his scholarly career, from 1925 as Professor of English language and older English literature at Charles University, Prague, followed by two decades of active retirement in which he was a well-known figure in European linguistics.

Among Trnka's major works within the field of English studies are a monograph on the historical syntax of the English verb (Trnka, 1930) and another monograph on Modern English phonology (Trnka, 1935). The latter work was a pioneering accomplishment; it was in fact the first such treatise to appear, and it was followed by other such prewar works within the Praguean trend (e.g., a monograph on Danish phonology by André Martinet, 1937).

In his breadth of study in the field of English studies and general linguistics Trnka was rather reminiscent of Otto Jespersen. Throughout his active scholarly life Trnka published on a wide variety of subjects within descriptive English grammar and phonology, notably on word classes and on word formation (an area in which Jespersen had not arrived at a fully satisfactory approach). Trnka developed a theory of word classes in English according to which nouns and verbs were constituted morphologically – by the inflectional categories associated with them. In his last work (Trnka, 1990) he delved into the relationship between language and society, like Jespersen and Sommerfelt before him.

Along with his position in English studies, Trnka was engaged in general linguistics, being one of the founders of the Prague school. He contributed substantially to the exploration of the notion of **contrast** at all levels of language structure, and thus worked along similar lines as Trubetzkoy and Jakobson in the prewar period, though his contribution has probably been somewhat overlooked in comparison to those of his two colleagues. Unlike them, however, he became a major force in the revival of the Prague school after World War II, with its emphasis on functionalism. He then went into the study of lexical meaning, a topic that was not otherwise much cultivated by structural linguists. In Trnka's view, a language system contains a finite (though high) number of lexical slots – 'empty squares' – each of which can be charged with meaning and thus can be studied at a meaning level. This approach to semantics is somewhat akin to but also interestingly different from that of Hjelmslev, who more or less at the same time had presented his own, much-debated ideas about content form and content substance.

Trnka was among the few early structuralists who, like Twaddell in the Bloomfield school, widened the scope of modern general linguistics so as to include language diachrony. Within historical phonology he wrote on Indo–European and Proto–Germanic phonology, including an analysis of the structural properties of Runic writing, and he addressed the great vowel shift in English.

Trubetzkoy, Nikolai Sergeievich, Prince (1890–1938)

N Kerecuk, London, UK

© 2006 Elsevier Ltd. All rights reserved.

Nikolai Sergeiievich Trubetzkoy, a Russian philologist, was born in Moscow in 1890 of a noble family. His father, Prince Sergei Trubetzkoy, was a professor of philosophy and rector of the University of Moscow. After graduating from Moscow University, where he read Sanskrit and philology, Nikolai Trubetzkoy pursued his Ph.D. in Sanskrit and historical linguistics at Leipzig University. His teachers were Neogrammarians, and he came to meet other fellow students, such as L. Bloomfield and L Tesnière. Subsequently, he taught at Moscow University (1915–1917), Rostov (1918–1919), and Sofia, Bulgaria (1920–1922). He was forced to flee Russia at the time of the October Revolution. From 1923 on, he was a professor of Slavic philology at the University of Vienna. He died in Vienna in 1938.

As a Russian philologist, and in tandem with intellectual climate in the old Russian empire of the early 1920s, Trubetzkoy based much of his work on the heritage of language studies, linguistics, and philology in the old Russian empire that evolved especially in the second half of the 19th century. There was a substantive migration of concepts and amassed data to the Prague Linguistic Circle and European centers before they crossed the Atlantic with Jakobson and others. After the demise of the Soviet Union, access to materials and archives was greatly facilitated, which has allowed broader research.

Trubetzkoy began his writings about folk poetry and myth within the spirit of the time. For example, in 1905, he wrote about a Finnish song, 'Kulto neito,' representing pagan customs; in 1906, he wrote on the mythical character Zolotaia Baba ('Golden Woman'); in 1908, he focused on the parallels of the myth of the origin of stone/earth between the Caucasian and Phyrgian peoples. The history of mythical thinking and mythology was a common pursuit in both western and eastern Europe throughout the 19th century.

He also wrote about the collection of linguistic and cultural information on the many tribes and

Along with his position in English studies, Trnka was engaged in general linguistics, being one of the founders of the Prague school. He contributed substantially to the exploration of the notion of **contrast** at all levels of language structure, and thus worked along similar lines as Trubetzkoy and Jakobson in the prewar period, though his contribution has probably been somewhat overlooked in comparison to those of his two colleagues. Unlike them, however, he became a major force in the revival of the Prague school after World War II, with its emphasis on functionalism. He then went into the study of lexical meaning, a topic that was not otherwise much cultivated by structural linguists. In Trnka's view, a language system contains a finite (though high) number of lexical slots – 'empty squares' – each of which can be charged with meaning and thus can be studied at a meaning level. This approach to semantics is somewhat akin to but also interestingly different from that of Hjelmslev, who more or less at the same time had presented his own, much-debated ideas about content form and content substance.

Trnka was among the few early structuralists who, like Twaddell in the Bloomfield school, widened the scope of modern general linguistics so as to include language diachrony. Within historical phonology he wrote on Indo–European and Proto–Germanic phonology, including an analysis of the structural properties of Runic writing, and he addressed the great vowel shift in English.

Nikolai Sergeiievich Trubetzkoy, a Russian philologist, was born in Moscow in 1890 of a noble family. His father, Prince Sergei Trubetzkoy, was a professor of philosophy and rector of the University of Moscow. After graduating from Moscow University, where he read Sanskrit and philology, Nikolai Trubetzkoy pursued his Ph.D. in Sanskrit and historical linguistics at Leipzig University. His teachers were Neogrammarians, and he came to meet other fellow students, such as L. Bloomfield and L Tesnière. Subsequently, he taught at Moscow University (1915–1917), Rostov (1918–1919), and Sofia, Bulgaria (1920–1922). He was forced to flee Russia at the time of the October Revolution. From 1923 on, he was a professor of Slavic philology at the University of Vienna. He died in Vienna in 1938.

As a Russian philologist, and in tandem with intellectual climate in the old Russian empire of the early 1920s, Trubetzkoy based much of his work on the heritage of language studies, linguistics, and philology in the old Russian empire that evolved especially in the second half of the 19th century. There was a substantive migration of concepts and amassed data to the Prague Linguistic Circle and European centers before they crossed the Atlantic with Jakobson and others. After the demise of the Soviet Union, access to materials and archives was greatly facilitated, which has allowed broader research.

Trubetzkoy began his writings about folk poetry and myth within the spirit of the time. For example, in 1905, he wrote about a Finnish song, 'Kulto neito,' representing pagan customs; in 1906, he wrote on the mythical character Zolotaia Baba ('Golden Woman'); in 1908, he focused on the parallels of the myth of the origin of stone/earth between the Caucasian and Phyrgian peoples. The history of mythical thinking and mythology was a common pursuit in both western and eastern Europe throughout the 19th century.

He also wrote about the collection of linguistic and cultural information on the many tribes and

people of the Caucasus. This work was a part of a tradition of a series of archeological and geographic expeditions that became a common activity by the second half of the 19th century in the Old Russian Empire and continued into the 20th century. In 1930, in his 'Nordkaukasische Wortgleichungen,' Trubetzkoy set out sound correspondences between the east and west Caucasian languages with a historical description of their consonant systems.

Trubetzkoy had an equally keen interest in issues of sociology and the politics of language, nationalism, and national identity. He wrote a number of articles on these topics and was one of the main ideological figures of Eurasianism, a political ideological movement of Russian émigrés in the 1920s and 1930s. The movement was based on the principle that the territories of the Russian empire in eastern Europe and northern Asia constitute a geographic, cultural, and political unit that is neither Europe nor Asia. The followers of this movement were antagonistic to Western values and European culture and had a messianic stance. The movement opposed self-determination for the peoples of the Russian empire and regarded their cultures and languages as part of the Russian collective or common tradition. Trubetzkoy was concerned with and wrote about Russian self-awareness and national identity. Eurasianism influenced his works in philology and linguistics.

In 1928, Professor V. Mathesius invited Trubetzkoy to become a member of the Prague Linguistic Circle (founded in 1926), where he met R. Jakobson (1896–1982) again. R. Jakobson regarded Troubetzkoy as his mentor, and they became good friends. Jakobson spoke about this many times. Trubetzkoy became an active member of the Prague Linguistic Circle, along with V. Mathesius, R. Jakobson, S. Karchevskii, and Jan Murařosvký, among others. The correspondence between Trubetzkoy and Jabokson (Jakobson, 1975) offers a personal perspective of their interactions during this period.

It is claimed that Trubetzkoy formally introduced some basic concepts, including markedness and invariance, that later became common currency in 20th-century linguistics. Indeed, Trubetzkoy and others in the Prague Linguistic Circle had had contact with O. O. Potebnja's (1835–1891) theory and philosophy of language, which contains these concepts.

Trubetzkoy's ideas on phonology, morphology, and linguistic geography were developed from the period of the Prague Linguistic Circle. He published *Zur allgemeinen Theorie der phonologischen Vokalsysteme* in 1929, and articles followed on the phonological system, on phonology and linguistic geography in 1931, and on the state of phonology in 1933. His 1936 essay concentrated on the theory of phonological oppositions.

The posthumous publication of his *Grundzüge der Phonologie* in 1939 (translated into English in 1969; it contains his autobiographical notes and a bibliography) is considered to be an account of the main beliefs of the Prague Linguistic Circle. It was not completed during his lifetime. Trubetzkoy put forward the idea that phonemes or phonological units are abstract: Any sound, e.g., 'p,' may have many varieties in a speech community, yet is perceived and treated as the same sound. If the change of the sound produces a contrast or opposition (r/m in 'rat' and 'mat'), a different word with different meaning results, and the phoneme has a contrastive function. Trubetzkoy produced a classification system for all phonemes, describing their features by comparing some 200 phonological systems in his search for a system of relationships and universals. This is usually regarded as the basis for the subsequent refinement of the concept of distinctive features later developed by R. Jakobson. In this work, Trubetzkoy also considered the possibility of the creation of a phonetic system for an artificial language.

He advocated the existence of a 'common Russian' literary language encompassing other Slavic languages. He lectured and wrote on the historical and contemporary Slavic languages and literatures as a professor of philology. He confused Old Ukrainian with Middle Russian literature, particularly in his lectures in the 1920s.

Trubetzkoy wrote and lectured on other aspects of language and literature. He used the term 'morphophonology' in his treatment of morphology and grammatical categories and functions of language. His influence in structural linguistics as developed in the 20th century is a relevant component in the history of ideas in linguistics and literary studies.

Truth Conditional Semantics and Meaning

E Lepore, Rutgers University, Piscataway, NJ, USA

© 2006 Elsevier Ltd. All rights reserved.

From the early 20th century, beginning with the revolutions in logic begun by the German mathematician Gotlob Frege and the English philosopher Bertrand Russell, until the present, philosophers have speculated about the notion of meaning. A variety of such notions are in general use: natural meaning, as in 'smoke means fire' or 'those spots mean measles'; conventional meaning, as in 'a red traffic light means stop' or 'a skull and crossbones means danger'; intentional meaning, as in 'John means well,' or 'Frank means business.' Philosophical semanticists are preoccupied with a different notion of meaning, however: Linguistic meaning is involved in the utterances of 'the words "bachelor" and "unmarried man" are synonymous (have the same meaning)'; 'the word "bank" is ambiguous (has several meanings)'; 'the string of words 'colorless green ideas sleep furiously' is anomalous (has no meaning whatsoever)'; 'the sentence "All bachelors are unmarried" is analytic (true in virtue of its meaning alone)'; and more directly, 'what "La neve e' bianca" means is that snow is white.'

One problem surrounding linguistic meaning concerns its dual roles. The meaning of a word reaches out, as it were, into the world, but also retains an inwards relation to other words. The meaning of 'tomato' is related both to the world – tomatoes – and to other words it combines with, as in, 'Tomatoes are a fruit'; 'Are tomatoes a fruit?' 'Get me a tomato!' Whatever else meaning involves, these two diverse roles are essential. For if one knows the meaning of 'tomato,' one grasps how it applies to the world and also how to employ it in indefinitely many sentences – a phenomenon labeled the productivity (or creativity) of language.

Compositionality is invariably invoked to explain productivity: the meaning of a complex linguistic expression is a function of the meanings of its parts. Differences in meaning between 'A tomato is better than an apple' and 'An apple is better than a tomato'

Truth Conditional Semantics and Meaning

E Lepore, Rutgers University, Piscataway, NJ, USA

© 2006 Elsevier Ltd. All rights reserved.

From the early 20th century, beginning with the revolutions in logic begun by the German mathematician Gotlob Frege and the English philosopher Bertrand Russell, until the present, philosophers have speculated about the notion of meaning. A variety of such notions are in general use: natural meaning, as in 'smoke means fire' or 'those spots mean measles'; conventional meaning, as in 'a red traffic light means stop' or 'a skull and crossbones means danger'; intentional meaning, as in 'John means well,' or 'Frank means business.' Philosophical semanticists are preoccupied with a different notion of meaning, however: Linguistic meaning is involved in the utterances of 'the words "bachelor" and "unmarried man" are synonymous (have the same meaning)'; 'the word "bank" is ambiguous (has several meanings)'; 'the string of words 'colorless green ideas sleep furiously' is anomalous (has no meaning whatsoever)'; 'the sentence "All bachelors are unmarried" is analytic (true in virtue of its meaning alone)'; and more directly, 'what "La neve e' bianca" means is that snow is white.'

One problem surrounding linguistic meaning concerns its dual roles. The meaning of a word reaches out, as it were, into the world, but also retains an inwards relation to other words. The meaning of 'tomato' is related both to the world – tomatoes – and to other words it combines with, as in, 'Tomatoes are a fruit'; 'Are tomatoes a fruit?' 'Get me a tomato!' Whatever else meaning involves, these two diverse roles are essential. For if one knows the meaning of 'tomato,' one grasps how it applies to the world and also how to employ it in indefinitely many sentences – a phenomenon labeled the productivity (or creativity) of language.

Compositionality is invariably invoked to explain productivity: the meaning of a complex linguistic expression is a function of the meanings of its parts. Differences in meaning between 'A tomato is better than an apple' and 'An apple is better than a tomato'

are due solely to the manner in which the sentences are composed. In this regard linguistic meaning differs from other sorts of meaning. A red skull and crossbones doesn't mean *stop danger*; smoky spots don't signify *enflamed measles*; if John both means well and means business it doesn't follow he means good business.

Finite beings never have entertained nor will entertain or use more than finitely many sentences, but just as 'A tomato is better than an apple' and 'An apple is better than an orange' are sentences, so too is 'A tomato is better than an apple and an apple is better than an orange'; and just as 'The apple is rotten' is a sentence, so too is 'The apple that fell on the man is rotten,' 'The apple that fell on the man who sat under a tree is rotten,' and so on with no obvious end. Because our language includes devices of grammatical conjunction and relative clause construction, we are able to form new sentences from old ones. Whatever meanings are, they must fit together in accordance with the compositionality principle. The project becomes to settle on basic word meaning and to let sentence meaning be composed from simpler components.

Philosophers have tended to fix on one of the two main aspects of meaning to the detriment of other. A theory of meaning – a semantic theory – must explain how a word can perform both of its functions. So, for example, John Locke, the 17th century empiricist, concentrated on the inner aspects of meaning. For him meaning is mental; we use language to encode thought. Successful communication involves correctly decoding words heard into their corresponding associated ideas. So construed, the meaning of an expression is the idea associated with it in the mind of anyone who knows and understands the expression.

But focusing on inner aspects of meaning raises some issues. Suppose your idea of grass is associated in your mind with your idea of warm weather; would it follow that 'grass' has the idea of warm weather as part of its meaning, at least for you? This focus also ignores the public nature of meaning. We learn the meaning of words from others, and once conversant, we can determine whether others successfully understand us. If meaning is an associated idea, how does anyone learn it? Then there is the matter of compositionality. Suppose a speaker associates with the complex expression 'brown cow' the idea of fear; he is not, however, fearful of cows or brown things *per se*, only the brown cows. On an ideational semantics, the meaning of 'brown cow' is not predictable from the meanings of its parts.

In an effort to render meaning public, B. F. Skinner hypothesized that the correct semantics for a natural language is behavioristic: the meaning of an expression is the stimulus that evokes it or the response it evokes, or a combination of both, at the time it is uttered. The meaning of 'Fire!' might be as it were to run. But a fireman, or a pyromaniac, or an audience of a known liar or a play doesn't run when she hears 'Fire!' Does it seem plausible that such individuals mean something different by 'Fire!' than those who run do? Then too there is the persistent worry over compositionality. Suppose a speaker recoils when he hears 'brown cow' but not when he hears 'brown' or 'cow' alone. The terms' meaning then would be undetermined by the meanings of its parts. How then does a speaker learn its meaning and the meaning of indefinitely many other expressions that can host it?

Bertrand Russell, following J. S. Mill, pursued the intuition that linguistic items are signs of something other than themselves. He suggested that the meaning of an expression is what that expression applies to, thus removing meaning from the minds and bodies of its users and placing it squarely in the world. On a referential semantics, all that one learns when one learns the meaning of 'tomato' is that it applies to tomatoes, and to nothing else. The semantics is compositional: if 'red' applies to anything red and 'tomato' applies to any tomato, 'red tomato' applies to red tomatoes.

But what about words that apply to nothing, like the term 'unicorn'? What about the serious problem first pointed out by Frege, that two expressions may have the same referent without having the same meaning? For example, 'Samuel Clemens' and 'Mark Twain' name the same author, but they aren't synonyms. As Frege noted, one could believe that Mark Twain wrote *Tom Sawyer* yet disbelieve Samuel Clemens did, without being irrational. Some authors, e.g., J. S. Mill and S. Kripke, conclude that proper names lack meaning. After all, if one does not know the referent of a name, one does not reach for a dictionary but rather an encyclopedia. But the problem persists even for common nouns – paradigmatic meaningful expressions. The descriptions 'the 41st president' and 'the husband of Hillary Clinton' apply to the same person but are not synonymous. One can understand both without recognizing that they apply to the same individual. But if meaning is what one learns when one learns an expression and if meaning is reference, then we have a problem.

In the seminal semantic theory of Frege, inner and outer aspects of meaning are inextricably bound. Frege associates with each expression a referent. The referents of these parts contribute systematically to the truth or falsehood of sentences in which they occur. Thus the truth or falsehood of 'The 41st president is a Democrat' is determined by the referents of

its individual words and the way they are put together. Its overall significance is fixed by what the parts of the sentence 'stand for' in the world and by relations between those parts. It follows that if a word is replaced in a sentence with another having the same referent, its truth or falsehood will not change. So the outer condition is secured. But now worries about the inner aspects of meaning arise. If you believe that the 41st president is a Democrat, it doesn't follow you will believe that the husband of Hillary Clinton is one. So 'You believe that the 41st president is a Democrat' will be true, while 'You believe that the husband of Hillary Clinton is a Democrat' will be false. If meaning determines truth or falsity, meaning must involve more than reference.

Frege accounts for this problem with senses. The sense of an expression is, intuitively, not what is referred to by an expression but the way in which it is referred to. Each sense determines one reference, but to one reference there may correspond many senses. Central to his view is that senses are abstract objects and not ideas in people's minds as per Locke. The two belief sentences above can disagree in truth value because, although both are about Bill Clinton, they pick him out in distinct ways.

Frege doesn't address how we explain the reference of words. A natural albeit vague answer is in terms of the psychological capacities of users of a language: words mean what they do because of what speakers do with them. An example of this semantics is the logical positivism of the Vienna Circle in the 1920s and 1930s, according to which the meaning of a sentence is given by an account of what it would take to verify it.

The basic idea behind verificationism is that meaning must be a result of links between language and experience: some sentences have meaning because they are definable in terms of other sentences, but ultimately basic sentences, the observation sentences, have their meaning because of their direct connection with experience (in this case being reports of it rather than copies). The connections between the world and language come down to a connection between observation sentences, on the one hand, and experience, on the other. Speakers, then, refer to whatever objects they would identify as the referents, whether by description or by recognition. Although the circumstances under which 'triangular' and 'trilateral' apply are the same, speakers go about *verifying* those applications in different ways. This suggests that the meaning of an expression is determined by the verifiability of sentences containing it.

The case against verificationism was most ardently pressed by W. V. Quine in the 1950s. He followed the verificationists in linking meaning to experience, but he argued that experience relates not to individual sentences but to whole theories. Since meaning must be empirically available, Quine poses the question: What empirical evidence determines what certain utterances mean? He contends that the only acceptable evidence is behavioral, based on the demands of the publicity of meaning, and therefore shuns Fregean senses. But behavioral evidence cannot, he argues, determine whether a person's words mean one thing or another; alternative incompatible 'translations' of the evidence are always available. And so Quine infers his famous doctrine that translation is indeterminate: no facts determine what words mean, i.e., there are no meanings.

Confronted with the skepticism about meaning produced by the indeterminacy of translation (and the later Wittgenstein's work as well), Donald Davidson in the 1960s and 1970s made a significant effort to resuscitate meaning. Sharing Quine's sympathies with an outer criterion, Davidson attempted to account for meaning not in terms of behavior but on the basis of truth, which by then had come to seem more logically tractable than meaning due to the formal work of the Polish logician Alfred Tarski. In the 1930s Tarski defined truth for formal languages in terms of the relation of satisfaction holding between the parts of sentences and sequences of objects. Truth is thereby determined systematically by the satisfaction of sentential parts; Tarski could show how to formally derive, from axioms and rules, semantic theorems that specify conditions under which any sentence of the language is true.

Frege and Davidson agree about compositionality being non-negotiable, but Davidson spurns the troublesome notion of sense and instead employs a Tarskian theory of truth to 'serve' as a theory of meaning. In outline, his idea is that a semantic theory for a language should entail for any sentence a theorem that 'gives its meaning' while respecting compositionality. But how can we devise a semantics with these consequences? Davidson's insight was to replace 'means that' in a sentence like '"La neve e' bianca" means that snow is white' with 'is true if and only if.' Tarski had already shown how to prove such theorems. By exploiting Tarski's theory of truth as a semantic theory, Davidson rendered substantive the rough but venerable idea that to give the meaning of a sentence is to give its truth conditions.

But how can a truth conditional semantics explain away the phenomena for which Frege invoked senses in order to explain in the first place? The sentences 'The 41st president is a Democrat' and 'The husband of Hillary Clinton is a Democrat' share truth conditions; both are true just in case Bill Clinton is a Democrat. But they don't mean the same. In response, Davidson suggested that in order to devise an

adequate truth theory for any given speaker who uses these sentences, we must apply the constraints of radical interpretation, particularly, the 'principle of charity' – assume that on the whole speakers are truthful. Interpretation proceeds as follows: collect sentences a speaker 'holds true,' and devise a truth theory with theorems specifying the circumstances under which these sentences were held true as a consequence. According to Davidson, any such theory will prove a sentence like '"The 41st president is a Democrat" is true if and only if the 41st president is a Democrat,' but not '"The 41st president is a Democrat" is true if and only if the husband of Hillary Clinton is a Democrat', thus solving Frege's problem.

Most semanticists in the 1980s and 1990s doubted whether a truth theory could specify the meaning of any given sentence. Many recommended adding to a truth conditional approach a conceptual role (also cognitive role, computational role, and inferential role) semantics. To understand how and why, consider the following thought experiment: suppose each of two otherwise psychologically indistinguishable speakers says, 'I am 30 years old.' The references of their utterances of 'I' differ. This shows that if the meaning of 'I' is what each speaker who uses the word grasps, then meaning does not determine reference. For if meaning determines reference, then these speakers do not grasp the same meaning and therefore they must assign distinct meanings to 'I.'

Hilary Putnam and David Kaplan independently explain this phenomenon by distinguishing the character (or stereotype) of an expression from its referent in a context of use. The character of 'I' maps any context of use onto its user. This character is grasped by anyone who understands the sentence. The utterance's content is its truth condition. When each speaker says, 'I am 30 years old,' what they know may be the same – they have the same understanding – but what each says has different truth conditions.

So far two expressions can share the same character (or stereotype or whatever corresponds to what we know in virtue of which we understand) and yet these expressions can differ in reference and truth conditions, since, as we saw above, conversely, sentences with the same truth conditions, our Bill Clinton sentences, can differ on the understanding component of meaning. What are we to make of someone who understands both sentences, yet asserts the first while denying the second? We know Frege's solution appeals to senses, and we touched upon Davidson's effort with radical interpretation. The conceptual role semanticist argues, instead, that these two descriptions have distinct computational roles for the speaker.

In sum, there are two distinct ways of semantically individuating a speaker's words: according to truth conditions **and** according to computational roles. According to the way of truth conditions, the speaker believes that Bill Clinton is a Democrat and also believes he is not a Democrat. But his rationality is not impugned, since truth conditions do not exhaust understanding. According to computational role, the corresponding beliefs expressed by utterances of these sentences are distinct, since the descriptions have distinct computational roles. When his beliefs are individuated in terms of computational roles, he does not have contradictory beliefs.

While the idea of a conceptual role for an expression has been around in philosophy for some time, what they are and what form a theory of conceptual role is supposed to take is much less clear than the form of a truth theory. For conceptual role semantics to explain how your word 'tomato' and mine can be synonymous, our words must share conceptual roles, but this is extremely unlikely. As long as there is the slightest difference between us with respect to inferences we are prepared to draw from our word 'tomato,' their conceptual roles differ. But then it is difficult to see how sense could be made of communication. If we assign different meanings to 'tomato' because our conceptual rules are distinct, there is nothing in common to be communicated. If we assign the same meaning (and so, assign the same conceptual roles), there is no need for communication. Compositionality is no easier to understand with conceptual rolesemantics: the inferential roles of complexes need not be determined by the inferential roles of its components – take 'brown cow' again.

For Davidson, belief and meaning are interdependent. One of the lessons he draws is that nothing can genuinely have beliefs unless it also has a public language. Many philosophers have recoiled, both because they think it is undeniable that certain nonlinguistic creatures – such as dogs and apes – have beliefs, and because they hope meaning can be explained in terms of beliefs and other mental states. One such influential semantics is H. P. Grice's, who suggested that the meanings of sentences can be reduced to a speaker's intention to induce a belief in the hearer by means of their mutual recognition of that intention.

Grice's analysis of meaning consists of various parts. It begins with a notion of speaker meaning: A speaker S means something by an utterance if and only if S intends the utterance to produce an effect in an audience A by means of A's recognition of this intention. So, e.g., I discover a person so constituted that, when I tell him that whenever I groan in a certain way I wanted him to wink; thereafter, whenever he recognizes the groan (and with it my intention), he winks. Grice's underlying idea is that I did something

('made a groan') with intentions. First, I intended to produce the utterance (the groan); second, I intended my audience to recognize the utterance; third, I intended that they should recognize my intention to produce the utterance; and fourth, I intended that they should recognize that I intended them to form some new belief (or do some action, etc.). In these circumstances, according to Grice, my groan means to wink. The place of conventional meaning in Grice's conception of language appears to be that it constitutes a feature of words that speakers might exploit in realizing the intentions referred to in the analysis of speakers' meaning.

Although Grice's program is not as popular as it once was, the general idea of reducing meaning to the psychological states of speakers is now widely accepted (*contra* Quine, Davidson, Wittgenstein, and their followers). In this sense Griceans have returned to the 17th century's emphasis on inner over outer aspects of meaning. How much, in the end, semantic properties can be attributed to features of the human mind remains a deep problem for continued study.

Introduction

What are the kinds of thing that are capable of being true or false – of bearing a truth-value? This issue in metaphysics connects with central issues in the philosophy of language. As noted in Haack (1978: 79), it has been regarded as bearing on such topics as the semantic paradoxes, the motivation for many-valued logics, and the viability of Russell's theory of descriptions.

To judge by our loose talk, various kinds of thing are capable of bearing truth-value. The obvious candidates are sentences, statements, propositions, and beliefs. Suppose Sally asserts the English sentence (1):

(1) George W. Bush was president of the United States in 2003.

We might describe her as having made a true statement, as having (assertorically) uttered a true sentence, as having expressed a true proposition, or as having given voice to a true belief. But supposing that we regard truth and falsity as properties, might it not be the case that 'in the final analysis' only one candidate has these properties nonderivatively?

Consider for example the hypothesis that the truth or falsity of a belief derives from the truth or falsity of the proposition that is believed. This hypothesis can be supported by appeal to the standard analysis of the propositional attitudes. On this analysis, what is shared by, for example, the belief that Jones is in Manhattan and the desire that Jones is in Manhattan is the propositional content *that Jones is in Manhattan*. Now, if the truth of a belief derives from the truth of the proposition believed, we have a natural explanation of the phenomenon whereby the same state of affairs – in this case, Jones's presence in Manhattan – bears equally on the truth of the belief as on the satisfaction of the desire. The explanation would be that the semantic evaluation of the attitudes – their evaluation along the dimensions of truth, or satisfaction, or what have you – is in the first instance an evaluation of their propositional contents. In this way we see how we might support the hypothesis that beliefs have their truth-values derivatively.

The hypothesis that there is a primary bearer of truth-value is the hypothesis that one type of entity bears its truth-value nonderivatively. Which of the three remaining candidates – sentence, proposition, statement – fits this job description?

('made a groan') with intentions. First, I intended to produce the utterance (the groan); second, I intended my audience to recognize the utterance; third, I intended that they should recognize my intention to produce the utterance; and fourth, I intended that they should recognize that I intended them to form some new belief (or do some action, etc.). In these circumstances, according to Grice, my groan means to wink. The place of conventional meaning in Grice's conception of language appears to be that it constitutes a feature of words that speakers might exploit in realizing the intentions referred to in the analysis of speakers' meaning.

Introduction

What are the kinds of thing that are capable of being true or false – of bearing a truth-value? This issue in metaphysics connects with central issues in the philosophy of language. As noted in Haack (1978: 79), it has been regarded as bearing on such topics as the semantic paradoxes, the motivation for many-valued logics, and the viability of Russell's theory of descriptions.

To judge by our loose talk, various kinds of thing are capable of bearing truth-value. The obvious candidates are sentences, statements, propositions, and beliefs. Suppose Sally asserts the English sentence (1):

(1) George W. Bush was president of the United States in 2003.

We might describe her as having made a true statement, as having (assertorically) uttered a true sentence, as having expressed a true proposition, or as having given voice to a true belief. But supposing that we regard truth and falsity as properties, might it not be the case that 'in the final analysis' only one candidate has these properties nonderivatively?

Consider for example the hypothesis that the truth or falsity of a belief derives from the truth or falsity of the proposition that is believed. This hypothesis can be supported by appeal to the standard analysis of the propositional attitudes. On this analysis, what is shared by, for example, the belief that Jones is in Manhattan and the desire that Jones is in Manhattan is the propositional content *that Jones is in Manhattan*. Now, if the truth of a belief derives from the truth of the proposition believed, we have a natural explanation of the phenomenon whereby the same state of affairs – in this case, Jones's presence in Manhattan – bears equally on the truth of the belief as on the satisfaction of the desire. The explanation would be that the semantic evaluation of the attitudes – their evaluation along the dimensions of truth, or satisfaction, or what have you – is in the first instance an evaluation of their propositional contents. In this way we see how we might support the hypothesis that beliefs have their truth-values derivatively.

The hypothesis that there is a primary bearer of truth-value is the hypothesis that one type of entity bears its truth-value nonderivatively. Which of the three remaining candidates – sentence, proposition, statement – fits this job description?

The Case for the Sentence as the Primary Bearer of Truth-Value

Consider first the sentence. One reason for regarding sentences as the primary truth bearers has to do with a traditional understanding of the aim and scope of logic. Logic is traditionally taken to be (or include) the study of the entailment relation, where a set of sentences of a language *L* entails a sentence *S* of *L* iff *S* is true on every interpretation on which all of the members of are true. Since this talk of 'truth on an interpretation' applies to sentences (well-formed formulas), it can be argued that logic itself gives us a motive to treat (atomic) sentences as having their truth nonderivatively (*see* **Logical Consequence**).

A second consideration in support of the sentence is that certain theories of truth seem to require, or at least to work best with, sentences as the primary bearers of truth. Consider for example those theories on which truth is a relation of correspondence between the facts and the truth bearers (whatever they are). Such theories typically require that candidate truth bearers have a structure that mirrors that of the facts; and it is arguable that sentences are the most apt candidate here (see e.g., Wittgenstein, 1922). So, too, Tarski's (1944, 1956) semantic theory of truth defines truth in terms of satisfaction, and goes on to characterize satisfaction in a way that makes use of various quasilinguistic distinctions, including that between names and predicates. This, too, appears to call for sentences as the primary bearers of truth.

It is worth noting, though, that neither of the foregoing arguments from the theory of truth is decisive in establishing the sentence as the primary bearer of truth. For example, on at least some conceptions of propositions, propositions can play the roles required by either of the above theories of truth. (For example, the argument from the correspondence theory of truth could be taken to rule out propositions only insofar as these are taken to be unstructured entities: sets of possible worlds, for example.) In addition, there are those theorists who, though rejecting both the sentence and the proposition as the primary bearer of truth, nevertheless endorse Tarski's semantic theory of truth: one thinks here of Davidson's (1967) attempt to square Tarski's theory with a view on which the statement is the primary bearer of truth.

Context and the Question of Truth Bearers

The sentence proposal is not without its share of difficulties. These can be seen when we turn attention from the formal languages typically studied in logic to natural languages. The main problem concerns context sensitivity. A sentence such as (2) is true or false according to who used it, and when.

(2) I am tired

So if sentences are the primary bearers of truth, we face a dilemma. Suppose that sentences which (like [2]) contain a context-sensitive component bear a truth-value. Then such sentences will have to be treated as having a truth-value that changes over time, according to the context of use. But the idea of a truth bearer that changes its truth-value over time is incompatible with the prevalent view (found in Frege, 1918 and elsewhere) that truth bearers have their truth-value timelessly. Suppose then that sentences like (2) do not bear a truth-value. To retain the sentence-as-primary-truth-bearer view, sentences must be found that do bear a truth-value. One natural suggestion comes in the form of Quine's (1960) 'eternal sentences': the truth bearers are those sentences whose truth-value is unaffected by any change of context. But, given other plausible assumptions, the 'eternal sentence' view has the revisionary implications, first, that the vast majority of sentences of everyday discourse fail to have a truth-value, and second (and as a result), that most speakers will have a hard time formulating truth-value-bearing sentences.

Presented with this dilemma, the defender of the sentence might think to advert to the distinction between sentence types and tokens. Then the phenomenon of context sensitivity might be taken to establish that it is not sentence types, but rather sentence tokens, that we evaluate for truth. For instance, Mary's utterance of (2) at noon, and her utterance of (2) at midnight, will present type-identical but token-distinct sentences – in which case we can treat the two sentence tokens as differing in truth-value, while allowing that each token has its truth-value timelessly. (If Mary was tired at midnight of the night of her midnight utterance of [2], then it is **always true** that she was tired then, and her midnight token of [2] is timelessly true.) But it is unclear whether the appeal to the type/token distinction provides a solid defense of the sententialist view of truth bearers. For one thing, it is natural to think that logic deals with sentence types rather than tokens, in which case the sentence token proposal is in tension with the logic-based motivation for the sentence view. For another, it is unclear whether the appeal to the type/token distinction gives us a reason to prefer the sentence token, as opposed to the statement or the proposition, as the primary bearer of truth. Indeed, it is plausible to suppose that the core lesson of context sensitivity is that it is not sentences themselves (whether construed as types or tokens), but what is expressed by the use

of a sentence on a given occasion, that is evaluated for truth.

This understanding of the lesson of context sensitivity has motivated many to look beyond the sentence. Some endorse the proposition, conceived as what is yielded by a semantic evaluation of utterances, as the primary truth bearer. Others, hesitant to endorse propositions given their abstractness and/or the difficulties involved in formulating their individuation conditions, have opted instead for the statement as the primary truth bearer. Since any utterances of e.g., (2) by distinct speakers, as well as any sufficiently temporally distinct utterances of (2) (even by the same speaker), express different statements, treating the statement as the primary truth bearer provides a natural accommodation of context sensitivity. But the relative superiority of the statement to the proposition depends on the controversial claim that statement individuation will be less problematic than, and in any case independent of, proposition individuation.

Ramifications of the Debate about Truth Bearers

As noted at the outset, the dispute over the primary bearer of truth-value bears on various issues in philosophical logic, the philosophy of logic, and the philosophy of language.

Consider for example the class of paradoxes which are often characterized as the 'semantic' paradoxes. The paradigmatic example is the so-called liar paradox, involving a sentence such as the following:

(L) This sentence is false

(For ease of exposition I will speak of sentences, rather than of types or tokens; but the point can be made either way.) If sentences are the primary bearers of truth, we might expect that (L) must be ascribed a truth-value. (This depends on the additional assumption that if sentences are the primary bearers of truth then all sentences must bear a truth-value.) But of course (L) is paradoxical: if it is false then it is true, and if it is true then it is false. Proponents of the sentence-as-primary-vehicle-of-truth view might well take the lesson of the liar to be that we need a logic that permits of more than two truth-values: the third value could be neither true nor false. Alternatively, the lesson of the liar might be that we should reject the claim that it is sentences, as opposed to statements or propositions, that are the primary bearers of truth: the claim would then be that an utterance of (L) does not express a proposition or make a statement. (Admittedly, both reactions ought to be assessed in terms of the acceptability of their implications, as well as their adequacy as an account of the semantic paradoxes more generally.)

The issue of truth bearers is also relevant to the viability of Russell's theory of descriptions. On the assumption that semantic evaluation is the evaluation of sentences, Russell concluded that sentences containing a definite description – for example, sentences of the form 'The *F* is *G*' – ought to be analyzed as implicitly quantificational, in the manner of 'There is something, *x*, that is *F* and *G*, and anything that is *F* is identical to *x*.' One of the advantages of this analysis is that it can preserve the meaningfulness and truth evaluability of such sentences even if there is no single thing that is *F*. But Strawson (1950) regarded Russell's proposed analysis as plainly artificial: among other things, it requires us to suppose that the grammatical subject of the sentence ('The *F*') is not its logical subject (which, on Russell's analysis, would be the predicates or propositional functions '*x* is *F*' and '*x* is *G*'). On Strawson's diagnosis, Russell was led to such a plainly artificial analysis by his assumption that semantic evaluation is the evaluation of sentences. Strawson rejected this assumption in favor of the view that semantic evaluation is the evaluation of statements; and having done so, he urged that we do not conflate the issue of truth evaluability (a feature of statements) with the issue of meaningfulness (a feature of words and sentences). Thus, on Strawson's analysis, utterances of sentences of the form 'The *F* is *G*' fail to express a statement (and so fail to be truth evaluable) if there is nothing in the relevant context that is uniquely *F*; but even so the sentence uttered would not thereby cease to be meaningful, since meaningfulness is a matter of the rules for the proper use of expressions. In this way we see that issues pertaining to the primary bearer of truth-value have implications for the viability of Russell's theory of descriptions.

The Scope of the Issue

The debate regarding the primary bearers of truth is itself typically presented in connection with the doctrine that truth is a relation (or a property). As it has been formulated here, the issue concerns which entity bears truth-value nonderivatively, and this can seem to be the same as the question regarding which entity nonderivatively possesses the property of truth. One might wonder, then, whether the debate might be dissolved by following so-called minimalist or deflationary views of truth, according to which truth is not a relation or a property. But as noted in Haack (1978: 83–84), there are questions in the vicinity of the 'primary bearer' debate which survive the repudiation of truth as a property or relation. The key issue concerns

the application of formal logic to natural language. Consider the familiar *modus ponens* inference rule:

$$\begin{array}{l} p \\ \underline{p \rightarrow q} \\ q \end{array}$$

To apply *modus ponens*, we must find acceptable values for p and q. But when considering what counts as an acceptable value, we are forced to confront issues of sentential context sensitivity again. To wit: the inference from "I am tired now" and "If I am tired now, I should go to bed now" to "I should go to bed now," though valid if we keep fixed the time and speaker, equivocates (and so is invalid) if the speaker or time changes from one premise to the next. This has nothing to do with whether one regards truth as a relation; but it does appear to raise most, if not all, of the issues brought up by the primary-bearer debate.

Traditional Theories

'What is truth?' is a question often deemed to be so perplexing as to be unanswerable. Yet understanding truth is clearly important, as the concept seems to sit at the center of many debates, including those over the nature of knowledge, meaning, and logic. Theories of truth are divided over two basic questions: Does truth have a nature? And, if so, what sort of nature does it have? Traditional theories answer 'yes' to the first question and so attempt to give an answer to the second; deflationary theories deny that truth has a nature that needs a deep explanation. We'll canvass traditional and deflationary theories in turn.

The oldest theory of truth is arguably the correspondence theory of truth. The basic idea, which may have originated from Aristotle, is that true propositions correspond to the facts. Taken just by itself, this idea is a truism; correspondence theorists add flesh to its bones by spelling out the nature of 'correspondence' and 'facts' in different ways.

In the early 20th century, for example, Wittgenstein (1922) and Russell (1906) developed a version of the correspondence theory of truth according to which propositions were true in virtue of sharing a common structure with the facts. According to this view, the concepts that compose simple propositions like the *cat is on the mat* exhibit a certain form; and objects (cats, mats) and relations (*being on*) compose basic facts that also exhibit a logical form or configuration. Thus a proposition 'corresponds' to a fact just when they share the same form or structure (see **Figure 1**).

Although this sort of view seems to explain the truth of simple propositions about cats and mats well enough, it faces problems with other sorts of facts. Consider the true proposition that there are no unicorns. Is there a negative fact which makes this proposition true? It is unclear whether there are any such facts. In response to these sorts of worries, some philosophers, following Tarski (1943) have attempted to cash out the correspondence intuition

the application of formal logic to natural language. Consider the familiar *modus ponens* inference rule:

$$\frac{p \quad p \rightarrow q}{q}$$

To apply *modus ponens*, we must find acceptable values for p and q. But when considering what counts as an acceptable value, we are forced to confront issues of sentential context sensitivity again. To wit: the inference from "I am tired now" and "If I am tired now, I should go to bed now" to "I should go to bed now," though valid if we keep fixed the time and speaker, equivocates (and so is invalid) if the speaker or time changes from one premise to the next. This has nothing to do with whether one regards truth as a relation; but it does appear to raise most, if not all, of the issues brought up by the primary-bearer debate.

Traditional Theories

'What is truth?' is a question often deemed to be so perplexing as to be unanswerable. Yet understanding truth is clearly important, as the concept seems to sit at the center of many debates, including those over the nature of knowledge, meaning, and logic. Theories of truth are divided over two basic questions: Does truth have a nature? And, if so, what sort of nature does it have? Traditional theories answer 'yes' to the first question and so attempt to give an answer to the second; deflationary theories deny that truth has a nature that needs a deep explanation. We'll canvass traditional and deflationary theories in turn.

The oldest theory of truth is arguably the correspondence theory of truth. The basic idea, which may have originated from Aristotle, is that true propositions correspond to the facts. Taken just by itself, this idea is a truism; correspondence theorists add flesh to its bones by spelling out the nature of 'correspondence' and 'facts' in different ways.

In the early 20th century, for example, Wittgenstein (1922) and Russell (1906) developed a version of the correspondence theory of truth according to which propositions were true in virtue of sharing a common structure with the facts. According to this view, the concepts that compose simple propositions like the *cat is on the mat* exhibit a certain form; and objects (cats, mats) and relations (*being on*) compose basic facts that also exhibit a logical form or configuration. Thus a proposition 'corresponds' to a fact just when they share the same form or structure (see **Figure 1**).

Although this sort of view seems to explain the truth of simple propositions about cats and mats well enough, it faces problems with other sorts of facts. Consider the true proposition that there are no unicorns. Is there a negative fact which makes this proposition true? It is unclear whether there are any such facts. In response to these sorts of worries, some philosophers, following Tarski (1943) have attempted to cash out the correspondence intuition

Figure 1 Proposition corresponding to a fact.

in a way that avoids commitment to facts, negative or otherwise, by arguing that propositions are true in virtue of the reference of their parts to objects and properties. The success of this strategy, however, rests on whether a satisfactory account of reference can be given.

Many philosophers also have found fault with the correspondence theory because of worries that it leads to skepticism. According to these philosophers, it is difficult to understand how we could ever "step outside" all language and thought in order to check and see whether our propositions really correspond to the facts. Partly because of these misgivings, philosophers in the 19th century developed the coherence theory of truth (Bradley, 1893). According to the coherence theory, a proposition is true just when it is a member of a coherent system. Thus propositions aren't true on this view because of their relation to the mind-independent facts but because of their relation to each other. One benefit of this view is that it seems to provide an answer to skepticism. For as long as a proposition 'hangs together' with other propositions in the sense defined by the theory, it is true. We don't have to encounter the naked facts 'in themselves' to know what is true and what is false.

Coherence theories, however, have seemed overly permissive to many philosophers. As Russell (1906) famously pointed out, such views imply that any group of propositions – even ones that are obviously false – are true as long as they are mutually coherent. They therefore seem to make too many propositions true.

A third theory of truth was developed by the pragmatist William James (1909) following earlier work by Charles Peirce. According to James's pragmatist theory, a proposition isn't true because it copies or coheres with anything. For the pragmatists, propositions are tools, and good tools do good work. Thus, on this theory, a proposition is true just when it is practically justified. A proposition is practically justified in turn when it is useful for achieving our goals over the long run.

The pragmatist theory, however, seems to face an uncomfortable dilemma when asked to explain what makes a proposition useful. If what makes propositions useful is up to us, then again any old claim might turn out to be true. By contrast, if it isn't up to us, then it seems we must abandon pragmatism. Consider the proposition that my brakes are working in my car. Believing this guides me in making future useful predictions (if I press the brakes the car will stop). But presumably it is only useful for me to believe that the brakes are working if it is really true that they *are* working. But this is not something the pragmatist can say, since we just invoked truth to explain usefulness instead of the other way around.

Deflationary Theories

Deflationary theories of truth are so called because they deflate the pretensions of traditional theories which attempt to define the underlying nature of truth. Deflationists take the fundamental fact about truth to be

(T) The proposition that p is true if and only if p.

The basic idea is that this schematic principle (more or less, depending on the variety of deflationism involved) explains all there is to explain about truth.

Most deflationary views have two aspects. The first and arguably most central is the metaphysical thesis already mentioned that truth has no underlying nature. This is often put by saying that there is no property, or at least no substantive property, shared by all and only true propositions. Deflationists typically argue for this claim by trying to show that, contra the tradition, we needn't appeal to anything other than (T) to explain truth's involvement in knowledge, meaning and logic. The second aspect of any deflationary theory is a semantic thesis about the role, if any, the word "true" plays in our language.

The simplest form of deflationism is the redundancy theory of truth, and stems from work by Frege and possibly Ramsey (1927). On this account, we need no separate semantic explanation of truth, for 'it is true that p' is just another way to say 'p.' To say that it is true that roses are red, for example, is really just to say in different words that roses are red. Thus, we only *appear* to ascribe a property to a sentence or proposition when we say that it is true; we are in reality ascribing nothing as ascriptions of truth are simply superfluous or redundant; they add nothing to the content of what has already been said.

The redundancy theory faces two crippling problems. First, there are counterexamples to its central claim. Consider, to take just one example, the proposition that

(S) Everything that Socrates said is true.

Clearly, the claim that *Everything Socrates said is true* is not equivalent to the fragment that *Everything Socrates said*. Accordingly, all ascriptions of truth are not redundant as the theory demands.

The second problem for the redundancy theory and other early forms of deflationism concerns whether and how we generalize over schema (T) in order to offer a suitable definition of truth. Redundancy theorists had a problem offering such a definition because using ordinary objectual quantification, it is hard to see how one could convert (T) into a suitable explicit definition. The natural suggestion 'For any proposition p, the proposition that p is true if and only if p' isn't, strictly speaking, well formed, because 'p' is being used as two different types of variables. Where it appears as a conjunct by itself, on the right-hand side of (T), it is used as a proposition; but, on the left-hand side, it has the character of a name being completed by a predicate.

Contemporary deflationists have made numerous suggestions as to how to deal with these two problems. Like the redundancy theory, the minimal theory (Horwich, 1998) holds that (T) is the most fundamental fact about truth. But, unlike the redundancy theorist, minimalists believe that 'the proposition that snow is white is true' and 'snow is white' are only necessarily equivalent, not synonymous. Moreover, they can acknowledge that truth is property. It is just not a substantive or natural property that needs any sort of *metaphysical* explanation. Minimalists also reject the need for an explicit definition of truth. They argue that truth is instead implicitly defined by all the instances of (T), and that our grasp of the concept consists in our disposition to accept these instances. Finally, following Quine, minimalists hold that our concept of truth does serve an important purpose. Without it, rather than asserting (S) above, we would face the impossible task of expressing an indefinitely long conjunction, namely:

If Socrates said roses are red, then roses are red, if Socrates said violets are blue then violets are blue . . .

But with (T) in hand, we may say instead that for every object x, such that x = what Socrates said, then x is true. The minimalist concludes that the sole function of the concept of truth is to allow us to generalize over open-ended strings of claims like this.

One issue dividing contemporary deflationists concerns the proper bearers of truth. Disquotationalists (e.g., Quine, 1990) are skeptical about the existence of propositions and take sentences or even utterances, to bear truth. Hence, they take as their central principle not (T) but the disquotation schema

(D): "S" is true if and only if s.

So-called pure disquotationalists, following Field (2001), go even farther. They take the concept of truth to apply only to sentences that we understand. Other philosophers have objected that this is too stringent, as it seems that we can apply the concept to sentences we can't understand, as when I say that most of what Socrates said was true, even though I don't understand ancient Greek.

A pressing problem for any form of deflationism, first raised by Dummett (1978), is how to account for the normative role truth plays in thought and language. It is a truism that in asserting propositions and forming beliefs, we aim at the truth. That is:

(TN) Other things being equal, we ought to believe what is true.

But it is difficult to see how (TN), which deals with what ought to be the case, can be deduced from (T), which deals only with what is the case. Deflationists typically reply that (TN) is simply another example of the generalizing function of truth. That is, (TN) is simply short for a long conjunction of individual norms of the form:

(B) Other things being equal, we ought to believe p when p.

And (TN) can be deduced from (T) along with (B). The issue remains unclear, however. For the deflationist now faces the difficult task of explaining why we should accept all instances of (B) without invoking the fact she set out to explain: that it is good to believe what is true, that is, (T).

Alternative Theories

Recently, several different theories of truth have sprung up as alternatives to both traditional and deflationary views of truth. The identity theory (Dodd, 2000) holds that true propositions do not correspond to the facts but are rather strictly identical to facts. Primitivism (Davidson, 1990) holds that truth is a primitive, indefinable property that we cannot explain in simpler terms that don't already presuppose it. Finally, alethic pluralism (Wright, 1992; Lynch, 2004) holds that truth may come in more than one form, in that propositions in different domains might be true in different ways. Thus, propositions

about the physical world around us may be true by corresponding to the facts, whereas those about morality may be true in virtue of their coherence with other propositions. Thus, the pluralist rejects traditional theories in so far as they try to say that all propositions are true in a single way. But, unlike the deflationist, they hold that there are more facts about truth than (T). The main problem with such theories, however, is to spell out exactly what is in common between all these ways of being true; that is, to say what makes them all 'ways of being true.'

Tucanoan Languages

J Barnes, SIL International, Bogota, Colombia

© 2006 Elsevier Ltd. All rights reserved.

Overview

Classification

The Tucanoan languages of Colombia, Peru, Ecuador, and Brazil fall into two major groupings: Western Tucanoan (WT) and Eastern Tucanoan (ET). In the Eastern area, there are two languages that are very different from the other languages: Cubeo (Cub.) and Retuarã/Tanimuca (Tanimuca-Retuarã; Ret.). Waltz and Wheeler (1972: 128–129), recognizing this difference, chose to put Cub. in a category by itself, calling it 'Middle Tucanoan.' (In other publications, the term 'Central Tucanoan' is used, but is obviously not intended as a geographic term as Cub. is on the northern edge of the other ET languages.) Waltz and Wheeler, in their Proto-Tucanoan studies, referring to

the differences between Cub. and the other ET languages, said, "The data indicates a possible break between Cub. and Western Tucanoan some time later than that between the Eastern Tucanoan groups and Western Tucanoan." (1972: 128). Ret., which is spoken south of the main ET area, was not included in the study by Waltz and Wheeler. Strom commented (1992: 1) that there appears to have been considerable influence from the Yucuna language on Ret. Ramirez (1997: 17) classified Ret. as ET, but puts it in a subcategory of its own. Malone (1986: Sect. 9.1) said: "Cubeo and Retuarã group closest to each other, which is shown by innovations for the protoconsonants *b (in the environment $__V_1CV_2$, where C is bilabial [bil]), *s, *w, *y. Cub. tends to have more innovations in common with WT languages (*b/$__V_1C_{+bil}V_2$, *d/__i, __Vs, *y/__Vd), but also has some in common with ET languages (*d, *w); Ret. tends to have more innovations in common with ET languages (*d, *w), but also has some in common with WT languages (*b/$__V_1C_{+bil}V_2$, *d/__Vs). I consider these two languages to be Middle Tucanoan."

In Table 1, linguistically similar languages are grouped together, based on their development from Proto-Tucanoan (Malone, 1986: Sect. 9.1 & 9.2, and I have added Pisamira [Pis.] to her data). Barasano (Barasana) and Taiwano are listed as one (Bar.), as the only major difference between the two is in pitch-stress (Jones and Jones, 1991: 2). Retuarã and Tanimuca are listed as one, (Ret.), as they differ mainly in a few lexical items (Strom, 1992: 1). Population figures for Pis. are taken from González (2000: 374), for Wanano (Guanano; Wan.) are from Stenzel (2004: 23), and for Yurutí (Yuruti; Yur.) are from Kinch (personal communication). The rest of the population figures are taken from the Ethnologue.

Table 1 The Tucanoan language family and population figures

Languages and groupings	*Population figure*	*Abbreviations*
EASTERN TUCANOAN Group #1		
Wanano	1560	Wan.
Piratapuyo	1070	Pir.
Tucano	5000	Tuc.
Pisamira	46	Pis.
Tuyuca	815	Tuy.
Yurutí	850	Yur.
Waimajã/Bará	700	Wai./Bar.
Carapana	650	Car.
Tatuyo	350	Tat.
EASTERN TUCANOAN Group #2		
Siriano	310	Sir.
Desano	1760	Des.
Macuna	550	Mac.
Barasano/Taiwano	350	Bas.
MIDDLE TUCANOAN		
Cubeo	6150	Cub.
Retuarã/Tanimuca	300	Ret.
WESTERN TUCANOAN		
Koreguaje	2000	Kor.
Secoya	435	Sec.
Siona	300	Sio.
Orejón	300	Ore.

The last three in the list of ET languages in Group #1 (from Table 1), demonstrate a borrowing from Arawakan languages in the inclusion of a ubiquitous prefix *ka-*, which does not occur in the other Tucanoan languages. See Metzger (1998). Many other well-established borrowings are apparent in the languages, especially from Geral (Nhengatu) and Portuguese. More recent borrowings from Spanish and/or Portuguese, are freely incorporated into the languages and suffixed with the appropriate Tucanoan suffixes.

Location

The Tucanoan languages are spoken in the border regions of Colombia with Brazil, Peru, and Ecuador. The ET languages and Cub. are spoken in the state of Vaupés in Colombia and the state of Amazonas of Brazil. Ret. is spoken in the state of Amazonas in Colombia. See Figure 1. The WT languages are spoken to the west and southwest of the ET languages. Koreguaje (Kor.) is found in the states of Caquetá and Putumayo in Colombia, Secoya (Sec.) near the Putumayo River in Ecuador and Peru, Siona (Sio.) on both sides of the Putumayo River in Colombia and Ecuador, and Orejón (Ore.) south of the Putumayo River in Peru. See Figure 2.

Interrelationship

The ET people mainly define themselves by their language, which is the language of their father. Thus, a Tuyuca (Tuy.) woman, for example, might marry a Siriano (Sir.) man. Each would continue to speak his or her own language. The children learn their mother's language first, and later on switch to speak their father's language. The men in a Sir. village might marry women from different language groups, with the result that the children in the village grow up hearing from two to six languages. For a succinct analysis of the relationships between the different ET groups, see Aikhenvald (2002: 17–28). The Western and Middle Tucanoan groups are permitted, within specific kinship guidelines, to marry those who speak their own language. The Eastern and Middle Tucanoan language groups all share basically the same culture and belief systems, which differ in significant ways from the Western groups.

Figure 1 Eastern and Middle Tucanoan languages with approximate locations.

Language Features

Some of the more interesting features of the Tucanoan languages are the small number of consonants, nasalization and nasal spreading, the system of numerical classifiers, and the use of evidential suffixes on the verb. These, as well as other features, will be discussed below.

Phonological Characterestics

Vowels

The Tucanoan languages, with the exception of Ret., have the vowel inventory as seen in Table 2. Ret. has a five vowel system, lacking the /ɨ/ of the other Tucanoan languages. In all of the Tucanoan

Figure 2 Western Tucanoan languages with approximate locations.

languages there are oral vowels in oral syllables and nasal vowels in nasal syllables. The following examples illustrate the six vowel contrasts:

Tuy. (my field data):

(1) /baˈa/ 'disposable basket'
/beˈe/ 'to split'
/biˈi/ 'to be similar'
/boˈo/ 'to desire'
/buˈu/ '*tucunaré* fish'
/bɨˈɨ/ 'pirana'

The following examples illustrate the oral–nasal contrasts:

Bas. (Jones and Jones, 1991: 9; personal communication):

(2)	a/ã	wa/wã	'to go'/'to illuminate'
	e/ẽ	eho/ẽhõ	'type of jungle nut'/'cold (illness)'
	i/ĩ	i/ĩ	'that (in sight)'/3SING.MASC (PRONOUN)
	o/õ	oha/õhã	'to enter woods'/'to untie'
	u/ũ	udi/ũdĩ	'to inhale'/'be similar to'
	ɨ/ɨ̃	ɨhɨ/ɨ̃hɨ̃	'hereditary chief of a sib'/'to burn (fire)'

The vowel /ɨ/ is a high central unrounded vowel, which is realized phonetically as a back unrounded vowel in certain environments in Carapana (Car.) and Tatuyo (Tat.) (Gómez-Imbert, 2000: 326 and Barnes field data).

Vowel Sequences Sequences of two contiguous vowels within a morpheme reveal interesting patterns of symmetry. See the description of Sir. (Nagler and Brandrup 1979: 120–122), and also of Pis. (González 2000: 380–381), in which she explained that /i/ and /ɨ/ may precede low vowels in the sequences iV and ɨV; /u/ may precede the three vowels farthest from itself; /e/ and /o/ may precede other low vowels; and /a/ may precede all three high vowels.

Consonants

The inventory of consonants in the majority of the Tucanoan languages, charted according to their phonemic characteristics, is shown in Table 3.

For a functional analysis of the consonants in four of the ET languages, see Gómez-Imbert (2000: 327–328).

In the ET and Middle Tucanoan languages, the voiced consonants and /h/ have nasal variants in nasal morphemes.

All 12 of the consonants in Table 3 are found in Desano (Des.) and Pir. The following languages have

Table 2 Vowel inventory

Type	*Front*	*Central*	*Back*
High	*i*	*ɨ*	*u*
Low	*e*	*a*	*o*

Table 3 Consonant inventory

	Bilabial	*Alveolar*	*Palatal*	*Velar*	*Glottal*
Voiceless stops	*p*	*t*		*k*	*ʔ*
Voiced stops	*b*	*d*		*g*	
Voiced flap		*r*			
Voiceless sibilant		*s*			
Voiceless semivowels			*h*		
Voiced semivowels	*w*		*j*		

all but /ʔ/: Car., Pis., Sir., Tuy., and Yur. The voiceless affricate /tʃ/ is used in Pis. rather than the voiceless sibilant /s/. Waimajã/Bará (Waimaha; Wai.) and Tat. lack both /ʔ/ and /s/. Bas. and Macuna (Mac.) lack /ʔ/ and /p/.

Cub. lacks /ʔ/ as well as /g/, and has the voiceless affricate /tʃ/ rather than /s/. Ret. lacks /j/ and /g/, but has the palatal stop /dj/.

The speakers of languages that lack /p/ or /s/ employ those consonants both in loanwords and when speaking other Tucanoan languages.

Two Western Tucanoan languages, Kor. and Sio., have 24 and 18 consonants respectively. Kor. has no voiced stops, but rather has bilabial and alveolar nasals at those points of articulation, and has /ɲ/ rather than /j/. It includes /w̥/ in addition to /w/, three voiceless aspirated stops, two voiceless nasals, the voiced affricate /dʒ/, and six labialized consonants. Of the typical 12 Tucanoan phonemes, Sio. lacks /r/, but includes a 'soft' voiceless fricative written as /z/, plus the two nasals /m, n/, the voiceless affricate /tʃ/, and three labialized consonants /k^w, g^w, h^w/.

Sec., as with Sio., lacks /r/, but has the same 'soft' voiceless fricative written as /z/, plus /k^w/ rather than /g/, and /m/ rather than /b/, totaling 12.

Ore. lacks /w/ and /r/ ([r] is an allophone of /d/), and includes the voiceless affricate /tʃ/. (Adequate information on Ore. is lacking.)

Two ET languages, Tucano (Tuc) and Wan., have 15 and 16 consonants respectively. Wan., in addition to the typical 12 Tucanoan phonemes, includes the voiceless affricate /tʃ/ and three voiceless aspirated stops. For a description of the development of these additional consonants in present-day Wan. from Proto-Tucanoan, see Waltz 2002. In 1967, West and Welch analyzed Tuc. as having the 12 consonants in Table 3. In 2000, having observed a definite change in pronunciation from, and language attitude toward, what was /CV_1hV_1/ to /ChV_1/ (where C is a voiceless stop), they included voiceless aspirated stops in their analysis, bringing the total of Tuc. consonants to 15. Welch and West (personal communication) analyze the phonetic realization [ChV] as /ChV/, for example: /-kho/ 'large, FEM,' whereas Ramirez recognized only /CV_1hV_1/: /-koho/ 'large' (1997: 216). Ramirez also analyzed /r/ as an allophone of /d/, which results in his defining a total of 11 consonant phonemes for Tuc. (1997: 25). It is to be noted that West and Welch have studied Tuc. in Colombia, and Ramirez in Brazil. The distance between the two locations of study is so great, and contact between the two groups is so rare, that it is not surprising that there are some differences.

Syllable Patterns

The Middle and ET languages have one basic syllable pattern: (C)V. In Des., Piratapuyo (Pir.), Tuc., and Ret. there is an additional syllable pattern, one in which the syllable is closed with a glottal stop: (C)Vʔ. In all of the languages, (C)VV has been analyzed as two syllables: (C)V.V, except that Ramirez analyzed (C)VV as a bimoraic syllable (1997: 53–56). The WT languages have monosyllabic two-vowel clusters, and a syllable can be closed with a glottal stop in Kor., Sec., and Sio.

There is evidence in Pir., Tuc., and Tuy. that an unstressed vowel between consonants /s/ and /t/ is dropping out, creating the consonant cluster /st/.

Pir. (Klumpp and Klumpp, 1973: 116; Waltz, personal communication):

(3) /biásitu/ [biástu] 'pot for hot pepper'

Tuc. (Welch and West, personal communication):

(4) /baʔa-sɨté/ [baʔasté] 'eat and scatter (food)'

Tuy. (my field data):

(5) /ˈpaasɨti/ [páasti] 'to be tired/bored'

Suprasegmentals

The suprasegmentals in the Tucanoan languages are nasalization and tone or stress that is accompanied by high pitch.

Nasalization and Nasal Assimilation In all of the ET languages, nasalization is a feature of the morpheme. Root morphemes are either oral or nasal. Suffixes are either specified as oral or nasal, or they are unspecified for nasalization. Those that are unspecified

are oral following an oral morpheme, and nasal following a nasal morpheme. In all of the Tucanoan languages, nasal spreading is progressive, spreading from left to right. In the following example from Des., /-re/ 'specifier' is unspecified for nasalization:

Des. (Miller, 1999: 14):

(6) /igo-re/ [igoɾe] 'to her'
/bãrĩ-re/ [mãɾĩɾẽ] 'to us'

In the Middle Tucanoan language Cub., as in the ET languages, nasalization is a feature of the morpheme, but the nasal spreading rule is different. In Cub., nasality spreads through any suffix that begins with /b, d, j/. In Ret., nasal spreading is blocked by obstruents, and present analysis has indicated that it occurs within the metrical foot (Strom, personal communication).

In the WT languages, nasalization is a feature of the syllable and spreads through all suffixes that begin with /w, j, h, ʔ/. In addition, nasalization spreads through /dʒ/ in Kor. and through /h^{w}/ in Sio. (Information is lacking on Ore.)

Regressive nasal spreading, where it occurs, is very limited. In the WT languages, it spreads from a morpheme consisting of a single nasal vowel to the preceding suffix. In the ET languages, regressive nasal spreading takes place in Des. (Miller, 1999: 14–15), Sir. (Criswell and Brandrup, 2000: 399), and Bas. (Jones and Jones, 1991: 15–16), affecting a limited set of specific, single-syllable suffixes. The regressive spreading never goes beyond one syllable. In the Middle Tucanoan language Ret., regressive nasal spreading affects only the first-person singular morpheme, which is prefixed to the verb root (Strom, 1992: 20). To illustrate regressive nasal spreading, note what happens to the suffix /-bi/ 'negative' in the following examples:

Des. (Miller, 1999: 14):

(7) wẽhẽ-bĩ-rã
kill-NEG-PL.ANIM
'the ones who don't kill'

(8) wẽhẽ-bi-gɨ
kill-NEG-*sing*.MASC
'the one who doesn't kill'

Accent and Tone Of the 19 Tucanoan languages, 11 have tonal systems with high and low tone contrasting in identical or analogous environments. In Car., Tat., Mac., and Wai. (though perhaps not in Bar.), all four combinations of high and low on two syllable roots occur.

In Des., Tuy., and Yur., there is one accented syllable per phonological word, and it is associated with high pitch. Sec. and Sio. have a pattern of accent on alternate suffixes. Ret. has a system of multiple stress with rules that require epenthesized suffixes and stress shifts (Strom, 1992: 13–19).

Accent is a property of the morpheme in the following ET languages:

- Bas. (Gómez-Imbert and Kenstowicz, 2000: 421)
- Des. (Miller, 1999: 15)
- Ret. (Strom, personal communication)
- Sir. (Criswell and Brandrup, 2000: 398)
- Tuc. (Ramirez, 1997: 68)
- Tuy. (Barnes, 1996: 31)
- Yur. (Kinch, personal communication)

The literature indicates that accent is probably a property of the morpheme also in:

- Cub. (Morse and Maxwell, 1999: 11–12)
- Mac. (Gómez-Imbert, 2000: 331)
- Pis. (González, 2000: 382).

Grammatical Characteristics

Sentence

The sentence in Tucanoan languages obligatorily demands a verb. Sentence fragments are used, but they occur, for example, as abbreviated answers to questions, responses using question words, etc.

Word Order In the majority of the Tucanoan languages, the usual word order in declarative clauses is (S)(O)V, with variations according to discourse constraints. In Car., the preferred word order is (O)(S)V. Bas. exhibits the basic order OVS. Cub. also has (O)VS, but SV(O) occurs as frequently. Kor. is the only language that has a preferred word order in which the verb is initial: V(S)(O), although other word orders also occur. The pattern OV occurs in all the Tucanoan languages, and the languages exhibit other typical features of OV languages.

Case Markers Nouns in the role of grammatical subject are unmarked, and there are rules for when the complements are marked. In Ret., both an animate subject and an animate object may have the same marker /-re ~-te/. Where there could be confusion, it is avoided by word order: The subject precedes the object.

Ret. (Strom, 1992: 114):

(9) ernesto-te alvaro-te hedjobaa-rape
Ernest-HUM *Alvaro*-HUM *help*-PAST
'Ernest helped Alvaro'

Although the Tucanoan languages are almost exclusively suffixing languages, Car. and Tat. allow the complement, if it is a pronoun, to be prefixed to the

verb, and Ret. has a neuter complement pronoun that only occurs as a prefix. In the rest of the Tucanoan languages, if the complement-pronoun needs to be expressed, it occurs in a separate word along with the complement/specificity suffix (REC = recent past; EV = evidential; NON3 = nonthird person – evidentiality and nonthird person are concepts discussed later in this article).

Car. (Gómez-Imbert, 2000: 332):

(10) kɨ-ĩjã́-à-bõ
3sing.MASC-see-REC-EV:PAST.VISUAL.3sing.FEM
'she saw him'

Sir. ('Brandrup, personal communication):

(11) sĩ́-bĩ
give-EV:PAST.VISUAL.3sing.MASC
'he gave (it) (to me)'

(12) igó-re weré-bɨ
3sing.FEM-SPEC tell-EV:PAST.VISUAL.NON3
'I told (that) to her'

The specificity suffix, which marks significant participants and props in the discourse, does not always occur with nonpronominal direct objects. Noun incorporation is evident where the object precedes the verb root and is phonologically part of the verb word.

Des. (Miller, 1999: 109):

(13) diu-pi
egg-place.on.ground
'lay an egg'

Other nounverb combinations function as noun incorporation. Alternatively the noun may function as an independent complement (BEN = benefactive).

Tat. (Gómez-Imbert, 2000: 334):

(14) jɨ-pátu-kẽdõ̃õ-boha-ja /kẽdõ̃õ-ja pátu-re
1sing-coca-prepare-BEN-IMP /prepare-IMP coca-SPEC
'prepare coca for me' /'prepare the coca'

When it is clear from the context that the noun is the complement, it is not marked as such, as in the case of 'pigs' in the following example (ANIM = animate, a concept discussed in this article).

Tuy. (Barnes, unpublished text #157):

(15) ape-'bɨreko 'tuakũbũ-adacu,
other.day arrive.near.goal-FUT.1,2PL pig-PL
je'se-a ja'a-adara hĩ'ĩ-ra
eat-AFFIRM.1,2PL say-PL.ANIM
'the next day we will arrive near (the town) in order to eat pigs'

With few exceptions, indirect objects, experiencers, and benefactors are always marked with the complement/specificity marker (SEP = separation, i.e., uncertain; D = dimension).

Mac. (Smothermon and Smothermon, 1995: 72):

(16) pauru-re ĩo-gɨ
Pablo-SPEC show-sing.MASC
j-a jɨ
AUXILIARY.VERB-PRES 1sing
'I am showing (it) to Pablo'

Sio. (Wheeler, 2000: 187):

(17) jɨ'ʔɨ dɨ̃'hõ-de gõ'ʔã haʔ'si-gɨ-jã
1sing wife-SPEC bones hurt-certainty-SEP
'my wife's bones hurt' (lit. 'bones hurt my wife')

Des. (Miller, 1999: 144):

(18) jɨ-re suʔri
1sing-SPEC clothes
ãsũ-basa-ra-jẽ sãjã-bɨ
buy-BEN-NOM-CLASS: 2D.flexible put.on-EV:PAST.VISUAL.NON3
'I put on the dress (cloth) that was bought for me'

A separate set of suffixes identify location, time, instrument, and accompaniment (ACC).

Pis. (González, 2000: 387):

(19) wetʃe-pɨ
field-LOCATIVE
'in the field'

(20) jãbĩ-pɨ
night-LOCATIVE
'at night'

(21) wãbõ-bẽdã
hand-INSTR
'by hand'

(22) kɨ̃-bai-bẽdã
3sing.MASC-younger.brother-ACCOM
'with his younger brother'

Nouns

Nouns in Tucanoan languages may be divided into two basic categories: animate and inanimate. These two categories take different plural suffixes. Within the animate category, human and nonhuman categories also take different plurals. Most ET nonhuman animate nouns are inherently singular and take a plural suffix. Nouns that refer to animals, insects, or fish that generally are found in groups are inherently plural and take a singularizing suffix.

Sir. (Criswell and Brandrup, 2000: 408):

(23) diá diá-rí
river river-PL.INAN
'river' 'rivers'

Sir. (Criswell and Brandrup, 2000: 405):

(24) bãhĩ-gɨ̃ bãhĩ-rã
*child-sing.*MASC *child-*PL.ANIM
'boy' 'children'

(25) pãbũ pãbũ-ã̃
armadillo *armadillo-*PL.ANIM
'armadillo' 'armadillos'

(26) burúá burúá-bɨ̃
termites *termites-*SINGULARIZER
'termites' 'a termite'

WT animate nouns have three categories: general, singular (with a singular suffix that is either masculine or feminine) and plural (with a plural suffix).

Sio. (Wheeler, 2000: 185):

(27) 'zĩ 'zĩgɨ 'zĩgo 'zĩkʷa
'child' 'boy' 'girl' 'children'

Classifiers The Tucanoan languages all have a small set of animate classifiers and, in most of the languages, a larger set of inanimate classifiers.

Animate classifiers, which also function as animate nominalizers, include masculine singular, feminine singular, and plural. Most of the languages have past, present, and future forms for the animate nominalizers as is shown in Table 4 for Sir.

Sir. (Criswell and Brandrup, 2000: 408):

(28) buué-gɨ
*study-sing.*MASC
'he who studies'

(29) buué-dii-gɨ
*study-*PERFECTIVE*-sing.*MASC
'he who studied'

(30) buué-bu-gɨ
*study-*POTENTIAL*-sing.*MASC
'he who will study'

Typically each ET language has over 100 inanimate classifiers, plus many nouns that may also function as classifiers. Ramirez (1997: 109) says that Tuc. has only six classifier suffixes, which he calls "shape suffixes" (plus some 400 'dependent nouns'). The 'shape suffixes' that both West and Welch (2000: 428 and personal communication) and Ramirez have identified are a small set of classifiers that do not require a nominalizer between the verb root and the 'shape suffix,' as do the many Tuc. suffixes that correspond to classifiers found in other ET languages.

Table 4 Animate classifiers in Siriano (Criswell and Brandrup, 2000: 408)

Tense	*Singular, Masculine*	*Singular, Feminine*	*Plural*
Present	*-gɨ*	*-go*	*-rã*
Past	*-dii-gɨ*	*-dee-go*	*-dẽẽ-rã*
Future	*-bu-gɨ*	*-bu-go*	*-bũ-rã*

Inanimate classifiers in Tucanoan languages typically are suffixes that categorize the object(s) referred to in terms of some salient characteristic, such as shape or arrangement. For a complete description of Tuy. classifiers see Barnes (1990). Tucanoan classifiers have been variously described as noun classifiers or numeral classifiers. In the ET languages, they are suffixed to numerals, demonstratives, quantifiers, genitives, nouns, and to either nominalized verbs and/or descriptive adjectives, or, in the case of the WT languages, directly to these roots as nominalizers.

Des. (Miller, 1999: 37, 5, 45, 125, 38, 40):

(31) juhu-koaru
*one-*CLASS*:gourd*
'one gourd'

(32) iri-ru
*this-*CLASS*:oblong*
'this airplane'

(33) baha-bĩhĩ-ri
*a.lot-*CLASS*:thin.plane-*PL.INAN
'many knives'

(34) bɨ̃-ja-ru
*2sing-*GEN-CLASS*:oblong*
'your boat'

(35) jukɨ-kawe
*tree-*CLASS*:bent*
'crooked tree'

(36) oʔa-ri-boga
*sweep-*NOM-CLASS*:bundle*
'broom'

When classifiers are suffixed to nouns, they are in a relationship of General-specific, as in the following examples, where /dẽĩ/ is the 'miritı́' palm.

Cub. (Ferguson *et al.*, 2000: 361):

(37) dẽĩ-jɨ̃ 'palm tree'
dẽĩ-rɨ 'palm fruit'
dẽĩ-kũ 'cluster of palm fruit'
dẽĩ-jabe 'seed of the palm fruit'
dẽĩ-joka 'palm leaf'

The WT languages have from 17 (Sec.) to 30 (Kor.) classifiers. These classifiers are suffixed to nouns, as in the Cub. examples above, and to verbs and adjectives as nominalizers. They are sometimes found suffixed to numerals and demonstrative adjectives.

The more than 29 Ret. classifiers are suffixed to nouns, numerals, nominalized verbs and descriptive adjectives, and optionally to demonstrative adjectives.

Noun Modifiers Noun modifiers in Tucanoan languages may be divided into two major groups: limiting adjectives and nominalized adjectival verbs.

Limiting adjectives, which are numerals, genitives, demonstratives (anaphoric or exophoric), and quantifiers, are either separate words or roots that require suffixes.

Mac. (Smothermon and Smothermon, 1995: 39–40):

(38) hɨa-hibɨ
two-CLASS:*basket*
'two baskets'

(39) hɨ̃gɨ ĩ ja-gɨ
hammock *3sing*.MASC GEN-CLASS:*hammock*
'his hammock'

Yur. (Kinch and Kinch, 2000: 477):

(40) ai-wi
that(EXOPHORIC)-CLASS:*building*
'that house'

Des. (Miller, 1999: 45):

(41) baha-bẽ-rã
a.lot-NEG-PL.ANIM
'a few (people)'

Nominalized adjectival verbs take the place of descriptive adjectives in the traditional sense of the term. Stative verbs, such as 'to be red' and 'to be big,' do not always take the full range of verb suffixes, and yet they are used as verbs, as can be seen in the following example.

Tuy. (Barnes, unpublished text #82):

(42) 'jaa dia'poa baji'ro
*1*GEN *face* *very*
jĩ'ĩ-a
be.black-EV:PRES.VISUAL.NON3
'my face is really dark (from the sun)'

Nominalized adjectival verbs may serve as full constituents of the sentence, i.e., the noun that is being modified will not appear in the sentence if the referent is already clear. When the referent is an animate noun, an animate classifier is suffixed directly to the verb and functions as a nominalizer. In the case of an inanimate referent, some of the languages require that a nominalizer be suffixed to the verb before the classifier.

Wan. (Waltz and Waltz, 2000: 460):

(43) jã́-ĩdã
be.bad-CLASS:PL.ANIM
'bad people'

Bas. (Jones and Jones, 1991: 63):

(44) sũã-ri-hãĩ joa-ri-hãĩ
be.red-NOM-CLASS:2D *be.long*-NOM-CLASS:2D
ãbõ-a-ha jɨ
want-PRES-NON3 *1sing*
'I want a long red piece of cloth'

Cub. has a small class of descriptive adjectives, which function neither as nouns nor as verbs. Among these are: *big, small, old, dry,* and *curly* (Morse and Maxwell, 1999: 124). Des., Sir., and Tuc. each list a small number of adjectives, among which are: *big* and *small* (Miller, 1999: 51; Criswell and Brandrup, 2000: 410; Welch, personal communication). Sec. and Sio. also each have a small class of descriptive adjective roots, including *big* and *small*, and derive the rest of their descriptive words from other grammatical forms (Johnson and Levinsohn, 1990: 37–38; Wheeler, 1987: 116–117). In Ret., words that are traditionally thought of as descriptive adjectives function almost exactly like nouns, and thus are listed as nouns (Strom, 1992: 23–26). The rest of the Tucanoan languages derive descriptive words by nominalizing verb roots and/or suffixing gender/number or classifier suffixes. In many, but not all, cases, these function much as do relative clauses in other languages.

Cub. (Morse and Maxwell, 1999: 86):

(45) xidoxa-RI-xãrãwɨ
be.scary-NOM-CLASS:day
'a scary day'

Personal Pronouns All of the Tucanoan languages have the same system for personal pronouns. In the singular, there are four forms: first person, second person, third-person masculine and third-person feminine. In the plural, there are also four forms: first-person exclusive, first-person inclusive, second person, and third person.

Tat. exhibits a typical set as shown in Table 5.

Demonstrative Adjectives The Tucanoan languages are split as to whether they make a distinction

Table 5 Personal pronouns in Tatuyo (Gómez-Imbert, 2000: 341)

	Person	*Singular*	*Plural*
	exclusive		*hãã*
1		*jɨ̃ɨ*	
	inclusive		*bãdĩ*
2		*bɨ̃ɨ̃*	*bɨ̃hã́ã*
	masculine	*kɨ̃ɨ̃*	
3			*dã́ã*
	feminine	*kõõ*	

between singular and plural in the demonstrative adjectives for inanimate referents. Cub., for example, does not make the distinction: /i-/ means both 'this' and 'these'; /ãdĩ-/ means both 'that' and 'those.' The anaphoric pronoun /di-/ means both 'that' and 'those' (Morse and Maxwell, 1999: 96). Pluralization is indicated only on the classifier or noun that follows the demonstrative adjective. Tuy. does make the distinction as shown in Table 6, and thus number is indicated on both the demonstrative adjective and the classifier or noun which follows it.

Tuy. (my field data):

(46) ati-do'to
*'this-*CLASS*:large.bundle*
'this large bundle (of firewood, cane, etc.)'

(47) ate-do'to-ri
*this.*PL-CLASS*:large.bundle-*PL.INAN
'these large bundles (of firewood, cane, etc.)'

Verbs

Independent verbs in Tucanoan languages are minimally comprised of a verb root and an evidential suffix, or an imperative, interrogative, or future suffix. In Tat. and Car., the verb root may be prefixed by a pronoun, and, to a lesser extent, the same is true for Bas. and Wai. Mood is indicated by suffixes that occur between the verb root and the evidential suffix, and may include negative, contraexpectation, desiderative, and irrealis suffixes. Some aspects are also indicated by verb suffixes that occur between the verb root and the evidential suffix, and indicate, for example, the habitual, durative, completive, and iterative aspects. Other aspects are indicated by auxiliary verb phrases.

Auxiliary Verbs The most common use of an auxiliary verb is in expressions of the progressive aspect. The main verb is nominalized, and the auxiliary verb is suffixed by dependent or independent verb suffixes, including whatever aspect or mood suffixes may be appropriate to the situation.

Table 6 Demonstrative pronouns in Tuyuca (Barnes and Malone, 2000: 446)

Pronoun	*Singular*	*Plural/Noncountable*
Exophoric		
'this'	*ati-*	*ate*
'that'	*ii-*	*iye*
Anaphoric		
'that'	*tii-*	*tee*

Tuy. (my field data):

(48) 'waa-gɨ tii-'bĩ-wi
*go-*NOM*:sing.*MASC *do-*CONTRAEXPECTATION-EV:PAST.VISUAL*.sing.*MASC
'He was going, but . . .'

Compound Verb Roots Compounding of verb roots is rare in the WT languages and Cub., but common in Ret. and the ET languages, where up to four verb roots can be combined in one phonological word. See Gómez-Imbert (1988) for an explanation of three different types of compounding that typically take place.

Tat. (Gómez-Imbert, 1988: 107):

(49) yã̄ã̄-róka-kũ̄bũ̄-ehá
fall-strike-lie.immobile-arrive
'to fall, arriving at and striking (the ground), and being immobile'

Evidentiality Evidentiality is an obligatory feature of the independent verb word in the ET languages, as well as in Cub., Sio., and Sec. It is indicated by optional verb suffixes in Ret., and is indicated by means of auxiliary verbs in Kor.

Evidential suffixes in the ET languages carry information about present and past tenses, and subject, including person, number, and gender. The function of the evidential suffixes appears to vary somewhat between the languages, indicating one of the following:

1. How the speaker obtained the information: Bar. and Wai. (my field data); Bas., Car., Mac., and Tat. (Gómez-Imbert, 2000: 340); Des. (Miller, 1999: 64); Sir. (Criswell and Brandrup, 2000: 400); Tuy. (Barnes and Malone, 2000: 441); Yur. (Kinch and Kinch, 2000: 479),
2. The speaker's degree of knowledge of the situation: Tuc., according to Ramirez (1997: 121), or
3. the point of view of the speaker: Wan. (Waltz and Waltz, 2000: 456); Tuc., according to Welch and West (2000: 424).

Evidential suffixes in the Middle Tucanoan language Cub. and in the WT languages Sio. and Sec. convey tense and person information as in the ET languages, but they indicate the degree of certainty about the information rather than how the speaker obtained the information (Ferguson *et al.*, 2000: 363; Wheeler, 2000: 189; Johnson and Levinsohn, 1990: 66–70). There is no information available on Ore.

Ret.'s evidential system consists of three optional verb suffixes. The first is /-ko-/, by which the

Table 7 Evidentials in Siriano (Criswell and Brandrup, 2000: 400)

Tense		*Visual*	*Apparent*	*Secondhand*	*Assumed*
Past	NON3	*-bɨ*	*-jo*	*-juro*	*-kujo*
	3sing.MASC	*-bĩ*	*-jũbĩ*	*-jupɨ*	*-kũjũbĩ*
	3sing.FEM	*-bõ*	*-jũbõ*	*-jupo*	*-kũjũbõ*
	3PL	*-bã*	*-jũbã*	*-jũrã*	*-kũjũbã*
Present	NON3	*-a*	-	-	*-koa*
	3sing.MASC	*-bĩ*	-	-	*-kũbĩ*
	3sing.FEM	*-bõ*	-	-	*-kũbõ*
	3PL	*-bã*	-	-	*-kũbã*

speaker tells something that he knows is a fact because he has heard something take place, although he has not seen it. The second is /-rihi-/, by which the speaker indicates that he is stating an assumption. The third is /-re/, by which the speakers conveys that the information is secondhand (Strom, 1992: 90–91).

Kor. employs auxiliary verbs to indicate evidentiality. One indicates secondhand information and the other indicates a supposition on the part of the speaker (Cook and Criswell, 1993: 86–87).

Wan. (Waltz and Waltz, 2000: 457) and Des. (Miller, 1999: 67–68) use an auxiliary verb phrase for the 'apparent' evidential, which is equivalent in function to the apparent evidential suffix in Tuy. The cognate verb phrase in Tuy. is distinct from the apparent evidential; the auxiliary verb bears the witnessed evidential suffix, and indicates that the speaker visually observed the end result of an action or state. (See Barnes, 1984: 264). Thus, by looking into the empty house he says, 'They left,' literally saying, 'I see that they are ones who have left.' Tuy. also has a single-syllable evidential suffix that indicates 'apparent' actions or states that the speaker deduces from evidence. That single-syllable suffix would be used, for example, when concluding that a piece of fruit was **apparently** in the state of being ripe, or it would not have fallen off the tree on its own. In the text where the following example occurs, the speaker heard the fruit fall, but never saw it.

Tuy. (Barnes, unpublished text #137):

(50) yĩĩ-'ri-ga dĩ'ĩ-bĩ-a-ju
ripen-NOM-CLASS:3D *be*-CONTRAEXPECTATION-REC-EV:PAST.APPARENT.NON3
'apparently the fruit was ripe'

Malone has concluded that the apparent evidential in Tuy. developed as the Tuy. speakers moved from expressing speaker distance in time and space to emphasizing how the speaker obtained his information (Malone, 1988: 138).

Table 7 illustrates a typical Tucanoan evidential system.

As is typical of most of the ET languages, person markers distinguish between third person and non-third persons. In Table 7, NON3 includes first and second persons singular and plural, plus inanimate.

Note that two of the eight paradigms in Table 7 are totally incomplete. The present tense in Sir. only distinguishes between the visual and assumed evidentials. The largest and most complete set of paradigms described in the literature on ET languages is found in Tuy., where 8 of 10 paradigms are complete (Barnes, 1984: 258). One of the incomplete paradigms is missing only the NON3 suffix. The totally empty paradigm is the present secondhand slot where one would not expect a paradigm, since secondhand information is always reported as past. Note the use of present and past in the following examples:

Tuy. (my field data):

(51) Bar'ia a'ti-jo
Maria come-EV:PRES.VISUAL.*3sing*.FEM
'Maria is coming' (reported by a person outside the house who sees Maria coming)

(52) a'ti-a-jigo
come-REC-EV: PAST.SECONDHAND.*3sing*.FEM
'she is coming' (lit. 'I was told that she was coming'), (reported by a person inside the house who has not seen Maria, but who heard the other say that she is coming)

Two features of evidentiality that occur in all of the Tucanoan languages are (1) firsthand knowledge of the state or event and (2) secondhand knowledge, indicating that the only information the speaker has about what he relates is that which came from someone else. All other features such as direct or indirect evidence, and tangible or intangible evidence, or, in the WT languages: degree of certainty, can be subdivisions of point (1).

Future The WT languages express the future by means of the potential aspect. The Middle and ET languages express the future in modal terms. For example, Bas. uses one of three moods to indicate the future: avoidance, conjecture, and intention

Table 8 Probable and indefinite future suffixes in Yurutí (Kinch and Kinch, 2000: 480, and personal communication)

Person	*Probable future*	*Indefinite future*
1,2 sing.MASC	*-gɨaku*	*-gɨga*
1,2 sing.FEM	*-goaku*	*-goga*
1,2PL	*-roaku*	*-raga*
3sing.MASC	*-gɨaki*	*-gɨagawi*
3sing.FEM	*-goakugo*	*-goagago*
3PL	*-rakua*	*-ragawa* ∼ *-roagawa*
Inanimate	*-roaku*	*-roga*

(Jones and Jones, 1991: 88–92). The rest of the Tucanoan languages have from one to three sets of future endings, composed of two to three morphemes each, which together convey probability, supposition, or definite intention. A study of Table 8 reveals how more than one morpheme is typically used in the formation of the future tenses.

Yur. (Kinch and Kinch, 2000: 480):

(53) bẽ'dãbẽ-pɨ 'waa-gɨaki
*tomorrow-*LOCATIVE *go-*FUT.PROBABLE
'he will go tomorrow'

(54) ati-jã'bĩka jo'sa-gɨagawi 'kɨ̃ɨ̃
this-afternoon *hang.in.hammock-*FUT.INDEFINITE *3sing.*MASC
'probably he will rest in his hammock this afternoon'

Tucker, Archibald Norman (1904–1980)

J Kelly, Leeds, UK

© 2006 Elsevier Ltd. All rights reserved.

Archibald Norman Tucker, phonetician and Africanist, was born in Cape Town and studied at the university there. After postgraduate work in Daniel Jones's Department of Phonetics at University College, London., he took his Ph.D. there in 1929, and was then engaged by the Education Department of the Sudan government to collect and analyze material on the indigenous languages of that country. In 1932 he was appointed to the Department of Phonetics and Linguistics at the then London School of Oriental Studies, and in 1951 became Professor of East African languages at what had now become the School of Oriental and African Studies. He retired in 1971, though for some years after that could still be seen working in an office he had retained at the School. He died in Camden, London.

Tucker's range of language interests was enormous, covering virtually the whole of the eastern half of the African continent, from the Sotho-Nguni group of languages in the south to the languages of western Sudan. His early work experience had brought him to one of the few areas of Africa where three of the four African language phyla could be experienced and material collected. Moreover, his training as a phonetician lent authority to his phonetic records and observations; his paper on distinctive voice quality in some of the 'Nilotic' languages is among the first to draw attention to this feature. These circumstances made it natural for him to take an interest in language classification, his earliest essay on which appeared in 1940, to be followed by two others produced in collaboration with his SOAS colleague Margaret Bryan. These have been described by a present-day expert (Bender, 2000) as "a great landmark in Nilo-Saharan studies," though both the classificatory groupings and the nomenclature employed have in more recent times been to some degree superseded. In addition to this, Tucker's phonological analyses may be thought to lose something through his steady adherence to the phonemic principles of his early training. His prosodic treatment of part of Luganda phonology is one interesting exception.

His academic interests extended, within African linguistics, to matters of orthography, including tone marking, and, beyond linguistics, to folklore and anthropology, as instanced by his extensive collection of materials on the marriage customs and rites of the Luo people.

Location and Composition of the Tungusic Language Family: Sociolinguistic Data

Tungusic languages (former name: Manchu–Tungusic) are spoken in a wide territory that includes Central and East Siberia and northeast China (Manchuria). One language, Sibe (Xibe), is located in the Xinjiang province of China. There are 12 modern Tungusic languages (see Table 1).

There are also two languages attested diachronically: Jurchen, represented by some inscriptions and dictionaries (12th–15th centuries C.E.), and Manchu, the state language of the Qing empire in China (1644–1911 C.E.) that has an abundant corpus of various written texts (16th to the early 20th century C.E.), most of them translations from Chinese. For all practical purposes, Manchu can be considered an archaic dialect of Jurchen, although the two languages employ different writing systems. Jurchen used a cumbersome indigenous (inspired by Chinese and Khitan writing systems) script that included both semantographic and syllabic signs. Manchu, on the other hand, uses the modified version of the Mongolian alphabet. Classical Manchu is still used in private correspondence by Heilongjiang Manchu, Solon, and Dagur Mongolians.

All surviving Tungusic languages are endangered to a greater or lesser extent; some of them are on the brink of extinction. The only languages spoken in China that have a written form are (1) Heilonjiang Manchu, whose speakers use essentially Classical Manchu, and (2) Sibe, whose speakers use a modified version of Classical Manchu that includes certain Sibe colloquialisms, because Sibe is historically a dialect of Manchu. During the Soviet period, literary forms were created for almost all Tungusic languages spoken in Russia, but most of them turned out to be short-lived. Even those languages that still have literary forms (Ewenki, Ewen, and Nanai) have a rather narrow application.

Internal Classification

There have been several conflicting attempts to classify Tungusic languages, but the most convincing is the recent attempt by Stefan Georg (2004), in which he proposed two basic groups: Northern (Ewenki, Ewen, Solon, Neghidal, Udehe, and Oroch) and Southern (Nanai, Ulcha, Uilta, both Classical and Modern Manchu, Sibe, and Jurchen). Within the Northern group, the following three subgroups should be distinguished: Ewen, Ewenki–Solon–Neghidal, and

Table 1 Modern Tungusic languages

	Names appearing in Ethnologue	*Frequently used alternative names*	*Number of native speakers*[a]
Ewenki	Evenki	Elunchun	11 360
Ewen	Even	Lamut	7463
Solon	Evenki	Ewenke	17 000
Neghidal	Negidal		170
Kili	Kili	Kur-Urmi, Hezhen	40
Udehe		Udige	526
Oroch	Oroch		169
Nanai		Goldi	5292
Ulcha	Ulcha	Olcha	986
Uilta		Orok	89
Heilongjiang Manchu	Manchu		70
Sibe	Xibe	Xibo	26 760

[a]Estimates of native speakers based on Soviet census of 1989 and Chinese census of 1990.

the intermediate subgroup including Udehe and Oroch. The languages of the intermediate subgroup are basically the Northern Tungusic languages that were strongly influenced by the Southern Tungusic languages. The Kili language that was traditionally considered a dialect of Nanai also likely belongs to the Northern group (Doerfer, 1978a). There are two subgroups within the Southern group: the Nani subgroup, including Nanai, Ulcha, and Uilta; and the Manchu subgroup, which included Manchu (both Classical and Modern), Sibe, and Jurchen.

Wider Genetic Affiliation

There is a widespread belief that Tungusic languages are distantly related to Mongolic, Turkic, Korean, and Japonic languages, forming with them the Altaic family. However, this controversial relationship has never been demonstrated satisfactorily. It is most likely that numerous parallels between the Tungusic and other Altaic languages represent traces of centuries- or even millennia-long contacts.

Structure

All Tungusic languages are agglutinative (with some elements of fusion) languages with SOV word order, although Ewen in some cases has shifts to SVO order, apparently under a strong Russian influence. Thus, there is only suffixation and no prefixation. Almost all languages have a rich morphology, with a somewhat reduced version of it in the Manchu subgroup.

Phonology

Tables 2 and 3 show the vowels and consonants for the Podkamennaia Tunguska subdialect of the Southern Ewenki dialect, which is used as the basis of the modern literary language. Both vocalic and consonantal systems are representative of the whole family, although, of course, certain expansions and/or reductions can be observed in individual languages. Syllabic structure is V, VC, CV, and CVC. Stress is probably dynamic, although further research is necessary. All languages have vowel harmony.

All vowels can be either short or long except **e** (< diphthong *ia), which is always long. Vowel length is phonemic (cf. Ewenki *bu-* 'to die,' *bū-* 'to give'; *tūkala* 'name of a plant,' *tukala* 'earth, ground').

Table 2 Vowels in Tungusic languages

	Front	*Central*	*Back*
High	i,ī		u, ū
Mid	ē	ə, ə̄	o, ō
Low	a, ā		

Morphology

Overall, the Northern Tungusic languages have a richer morphology than the Southern Tungusic languages. Nouns in most Tungusic languages have categories of number, case, and possession, although possession is not present in the Manchu subgroup. The number of cases varies from 6 in Manchu to 13 in Ewen. There is a certain allomorphism in case suffixes, depending on the last consonant of a nominal stem and vowel harmony. Table 4 shows an Ewenki paradigm that includes 11 cases for the words *bira* 'river,' *dət* 'tundra,' and *oron* 'reindeer.'

Some Tungusic languages differentiate between alienable and inalienable possession (cf. Ewenki *dili-B* head-1PERS.sing.POSS 'my head' and *dili-ŋi-β* head-ALIEN-1PERS.sing.POSS 'head of an animal that I killed and have in my possession,' where alienable possession is indicated by the special affix -*ŋi*-). There is also a distinction between exclusive and inclusive first person plural pronouns (cf. Manchu *be* 'we without you' and *muse* 'we including you,' 'I and you').

In some languages, adjectives agree with the modified noun in number and case, as for example in Ewenki: ərū-l-dū bira-l-dū bad-PL-DAT.LOC river-PL-DAT.LOC 'in bad rivers'; adjectives stay uninflected in other languages, as in Nanai: *dāi xoton-sal-ƒiaƒi* big city-PL-EL 'from big cities.'

The verbal morphology is very complex. All languages differentiate between nonfinite and finite verbal forms. Verbs have the following categories: voice, aspect, mood, tense, person, and number. There are six moods, six voices, and ten different aspects in

Table 3 Consonants in Tungusic languages

	Bilabial		*Dental*		*Palatal*		*Velar*		*Glottal*

Tunisia: Language Situation

J Battenburg, California Polytechnic State University, San Luis Obispo, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

Although Tunisia is an Arab, African, and Mediterranean country that has long served as the crossroads between East and West, it possesses a level of linguistic and cultural homogeneity found in few other countries around the world. Tunisia has a population of approximately 10 million and literacy rate of 74%, and over 99% of Tunisians speak Arabic (Arabic, Tunisian Spoken). As with other Arab countries, diglossia exists in which Arabic is divided into 'higher' varieties (composed of Classical Arabic and Modern Standard Arabic) and 'lower' colloquial varieties, which themselves are represented by local dialects.

Classical Arabic is used in reciting the Koran while Modern Standard Arabic is employed in academic

lectures, literature, and political speeches. Modern Standard Arabic (MSA) is more commonly employed yet less formal than Classical Arabic. Tunisian Arabic, sharing features with Maghrebi Arabic also spoken in Morocco, Algeria, and Libya, forms with MSA a diglossia and occupies a lower standard than both Classical Arabic and MSA. Educated Arabic is another linguistic variety developing from the competition between Tunisian Arabic and MSA. Finally, French Arabic represents a mixture of French and Arabic.

Tunisian Berber speakers account for less than 1% of the population. Berbers are found in six small villages in the south of Tunisia: Chenini, Douiret, Guellala, Tamezret, Taoujout, and Zrawa. Berbers also continue to migrate back and forth between their villages and larger cities in Tunisia and France. Unlike the Berber varieties in Morocco and Algeria, Tunisian Berber is facing obsolescence because of widespread Arabic and French bilingualism as well as its relegation to use only among family and friends.

French, of course, remains the second language of Tunisia due to the establishment of the country as a French protectorate from 1912 to 1956 and the continued political, economic, and cultural ties that have existed since independence. While the curriculum in basic education has been Arabized, French is taught from the third year. In secondary school, French is the language of math and science instruction, while Modern Standard Arabic is used to teach the humanities. In practice, varieties of Arabic reflecting the diglossic continuum and French are commonly used in Tunisian education. While Arabization is continuing in government ministries and educational institutions, French also remains firmly established.

Other languages in Tunisia include English, German, and Italian. For the foreseeable future French will remain the dominant second language; however, there is an ongoing struggle between the spread of English and the continued use of French in Tunisia. The argument put forward by certain educators, journalists, and businesspeople in Tunisia and elsewhere in the Maghreb is that while French provides a window to the outside world, English opens a larger door. Discussion concerning modernization and privatization often leads to questions about language policy and planning decisions. German and Italian are additional languages commonly taught and used in Tunisia because of trade and tourism.

While Arabization will carry on within domains of Tunisian society, socio-economic cooperation with European Union countries indicates that Tunisia will continue to encourage multilingualism as a tool for development.

Tupian Languages

N Gabas Jr, Belém, Brazil

© 2006 Elsevier Ltd. All rights reserved.

The Tupí family is one of the largest families of languages of South America. It contains 10 branches, with a variety of languages in each branch. The first comprehensive classification of the Tupian languages was by Rodrigues (1964), and further improvements of his classification were made by Cabral (1996, 1997), Gabas (2000), Rodrigues and Cabral (2002), Rodrigues and Dietrich (1997), and Rodrigues (1966, 1980, 1985a, 1997). It is generally accepted that the point of origin of Tupian groups is the state of Rondônia, in the northwest part of Brazil. Rondônia is still the homeland of five Tupian branches – Arikém, Mondé, Puruborá, Ramaráma, and Tuparí – and of a few dialects (Amondawa, Karipuna, and Uru-eu-wau-wau) of the Kawahíb cluster of the Tupí-Guaraní branch.

Nine branches of the Tupí family are shown in **Table 1**, together with the languages that belong to each branch. Classification of the tenth branch of the Tupí family, Tupí-Guaraní, is shown separately, in **Table 2**, because of its complexity; the Tupí-Guaraní branch has the largest number of languages of the Tupí family (almost 50 languages, arranged in several subgroupings), and several of its members are spoken in countries other than Brazil. In **Table 1**, languages on the same line separated by a slash correspond to dialects of the same language; languages within parentheses correspond to alternate names for that

lectures, literature, and political speeches. Modern Standard Arabic (MSA) is more commonly employed yet less formal than Classical Arabic. Tunisian Arabic, sharing features with Maghrebi Arabic also spoken in Morocco, Algeria, and Libya, forms with MSA a diglossia and occupies a lower standard than both Classical Arabic and MSA. Educated Arabic is another linguistic variety developing from the competition between Tunisian Arabic and MSA. Finally, French Arabic represents a mixture of French and Arabic.

Tunisian Berber speakers account for less than 1% of the population. Berbers are found in six small villages in the south of Tunisia: Chenini, Douiret, Guellala, Tamezret, Taoujout, and Zrawa. Berbers also continue to migrate back and forth between their villages and larger cities in Tunisia and France. Unlike the Berber varieties in Morocco and Algeria, Tunisian Berber is facing obsolescence because of widespread Arabic and French bilingualism as well as its relegation to use only among family and friends.

French, of course, remains the second language of Tunisia due to the establishment of the country as a French protectorate from 1912 to 1956 and the continued political, economic, and cultural ties that have existed since independence. While the curriculum in basic education has been Arabized, French is taught from the third year. In secondary school, French is the language of math and science instruction, while Modern Standard Arabic is used to teach the humanities. In practice, varieties of Arabic reflecting the diglossic continuum and French are commonly used in Tunisian education. While Arabization is continuing in government ministries and educational institutions, French also remains firmly established.

Other languages in Tunisia include English, German, and Italian. For the foreseeable future French will remain the dominant second language; however, there is an ongoing struggle between the spread of English and the continued use of French in Tunisia. The argument put forward by certain educators, journalists, and businesspeople in Tunisia and elsewhere in the Maghreb is that while French provides a window to the outside world, English opens a larger door. Discussion concerning modernization and privatization often leads to questions about language policy and planning decisions. German and Italian are additional languages commonly taught and used in Tunisia because of trade and tourism.

While Arabization will carry on within domains of Tunisian society, socio-economic cooperation with European Union countries indicates that Tunisia will continue to encourage multilingualism as a tool for development.

The Tupí family is one of the largest families of languages of South America. It contains 10 branches, with a variety of languages in each branch. The first comprehensive classification of the Tupian languages was by Rodrigues (1964), and further improvements of his classification were made by Cabral (1996, 1997), Gabas (2000), Rodrigues and Cabral (2002), Rodrigues and Dietrich (1997), and Rodrigues (1966, 1980, 1985a, 1997). It is generally accepted that the point of origin of Tupian groups is the state of Rondônia, in the northwest part of Brazil. Rondônia is still the homeland of five Tupian branches – Arikém, Mondé, Puruborá, Ramaráma, and Tuparí – and of a few dialects (Amondawa, Karipuna, and Uru-eu-wau-wau) of the Kawahíb cluster of the Tupí-Guaraní branch.

Nine branches of the Tupí family are shown in Table 1, together with the languages that belong to each branch. Classification of the tenth branch of the Tupí family, Tupí-Guaraní, is shown separately, in Table 2, because of its complexity; the Tupí-Guaraní branch has the largest number of languages of the Tupí family (almost 50 languages, arranged in several subgroupings), and several of its members are spoken in countries other than Brazil. In Table 1, languages on the same line separated by a slash correspond to dialects of the same language; languages within parentheses correspond to alternate names for that

Table 1 Classification of nine branches of the Tupi family

Branch	*Language*	*Population*
Awetí	Awetí	100
Arikém	Arikém	Extinct
	Karitiána	170
Jurúna	Jurúna	210
	Xipáya	15 (two speakers)
Mawé	Mawé (or Sateré)	5800
Mondé	Aruá/Cinta-Larga/Gavião/Zoró	36/640/360/250
	Mondé (Salamãy)	3 (semi-speakers)
	Suruí	580
Mundurukú	Mundurukú	3000
	Kuruáya	10
Puruborá	Puruborá	20 (two semi-speakers)
Ramaráma	Karo (Arara)	170
Tuparí	Ayurú	40
	Akuntsu	7
	Makuráp	130
	Mekéns (Sakirabiat)	70
	Tuparí	200

language. In Table 2, language clusters are indicated by italics. These correspond roughly to dialects of the same language. The population numbers given in both tables, except where indicated, correspond to the actual number of speakers of the language.

Of the 10 branches of the Tupí family, the Tupí-Guaraní branch is the one mostly studied. Languages of this branch have a higher degree of lexical and morphological similarities to each other when compared to languages of other branches. Internal classification of the Tupí family is currently in the early stages, but what is known about languages outside the Tupí-Guaraní branch allows a few generalizations to be made about Tupian languages as a whole. Larger genetic relations between Proto-Tupí and other families of languages, especially Macro-Jê and Karíb, have been proposed by Greenberg (1987) and Rodrigues (1985b, 1999, 2000) (*see* **Macro-Jê; Cariban Languages**).

General Properties of Tupian Languages

From the point of view of phonetics and phonology, Tupian languages do not have intricate consonantal and/or vocalic systems. Rodrigues (1999: 112) has reported that consonant systems across the family vary from 10 to 19, and Rodrigues and Dietrich (1997) proposed that Proto-Tupí has a six-vowel system. It is common that languages of various branches have a phonological distinction between short and long vowels (cf., Jurúna and Xipáya, of the Jurúna branch; Mundurukú, of the Mundurukú branch; possibly all languages of the Tuparí branch; all languages of the Mondé branch; and Karitiána, of the Arikém branch). Furthermore, nearly half of the Tupian branches have languages with either a true tone system (the Mundurukú and Mondé branches and possibly the Tuparí and Jurúna branches) or a pitch-accent system (Arikém and Ramaráma branches). Stress in Tupian languages is predictable, occurring generally in the last syllable of words. Tupian languages also have a syllable structure that typically does not allow consonant codas word-internally, with the exception of the glottal stop and the glottal fricative. Thus, patterns of consonant-vowel-consonant (CVC) and vowel-consonant (VC) occur exclusively word-finally.

From the point of view of morphology, Tupian languages are agglutinative and isolating. Only a few linguistic categories are marked by affixes – for instance, pronominal prefixes, two or three valence-changing prefixes (causative, comitative causative, and detransitivizer or passivizer), modal markers (usually indicative and gerund), and diminutive/augmentative markers. Categories such as number, gender, tense, and aspect are syntactically marked by particles.

Word classes are well established and easily distinguishable from each other on morphological and/or syntactic/semantic bases. Typical word classes are nouns (including pronouns), verbs (transitive, intransitive and, sometimes, uninflected verbs), postpositions, and particles. Adjectives occur in only a few branches (Arikém, Ramaráma, and Mondé). In all other branches, a descriptive verb fulfills the function of 'attributes' and 'properties.' Core cases, with the possible exception of Tupí-Guaranian languages, are not morphologically marked. Oblique case marking is conveyed by postpositions, in postpositional phrases. Usually, four or five cases are marked (ablative, allative, dative, instrumental, locative), although languages such as Karo have a larger system; Karo has 12 different postpositions that are used to mark the ablative, abessive, adessive, allative, comitative, dative, dispersive, inessive, instrumental, locative, similative, and circumjective cases.

Nouns, with the exception of those for elements of nature, are categorized as either alienable or inalienable. Alienable nouns generally designate manufactured items, kinship terms, animals, and plants, and occur freely in noun phrases. Inalienable nouns include mostly body parts (and, in some languages, kinship terms), and must occur preceded either by a free noun or a personal prefix (or, in some languages, such as Karo, a personal clitic). The occurrence of positional demonstratives, which mark the lying, standing, sitting, and hanging position of the head noun, is common in Tupian languages. Positional

Table 2 Classification of the Tupí-Guaraní branch[a]

Subgroup	*Language and clusters*[b]	*Country*	*Population*
I	Ancient Guarani	Brazil	Extinct
	Chiriguano (Avá)	Argentina/Bolivia/Paraguay	15 000/35 000/2000
	Izoceño	Bolivia	15 000
	Guayakí	Paraguay	850
	Kaiwá	Argentina/Brazil/Paraguay	500/9000/10 000
	Mbyá	Argentina/Brazil	1000/2000
	Nhandéva	Brazil	4900
	Paraguayan Guaraní	Paraguay and border areas of Argentina and Brazil	4 000 000
	Xetá	Brazil	3
II	Guarayu	Bolivia	5000
	Sirionó	Bolivia	650
	Jorá	Bolivia	5–10
III	Lingua Geral Paulista	Brazil	Extinct
	Nheengatu	Brazil	3000
	Tupí	Brazil	Extinct
	Tupinambá	Brazil	Extinct
IV	Avá (Canoeiro)	Brazil	100
	Asuriní of Tocantins	Brazil	200
	Guajajára	Brazil	10 000
	Parakanã	Brazil	350
	Suruí of Tocantins	Brazil	150
	Tapirapé	Brazil	200–350
	Tembé	Brazil	100–200
	Turiwára	Brazil	Extinct
V	Anambé of Cairarí	Brazil	20
	Araweté	Brazil	80
	Ararandewára-Amanajé	Brazil	200 (extinct)
	Asuriní of Xingú	Brazil	65
		Brazil	70
VI	Apiaká	Brazil	?
	Kawahíb cluster		
	Amondawa	Brazil	50
	Karipuna	Brazil	12–15
	Juma	Brazil	9
	Tenharim	Brazil	260
	Uru-eu-wau-wau	Brazil	100
	Kayabí	Brazil	800
	Parintintin	Brazil	130
VII	Kamayurá	Brazil	270
VIII	North of the Amazon		
	Emerillon	French Guiana	200
	Wayampí (Oyampí)	Brazil/French Guiana	500/650
	Zo'é	Brazil	140
	South of the Amazon		
	Guajá	Brazil	350
	Aurê and Aurá	Brazil	2
	Urubú-Kaapor	Brazil	500

[a]Data from Rodrigues and Cabral (2002).
[b]Names in italics indicate language clusters.

demonstratives are found in Mekéns, Karitiána, Mawé, and Mundurukú.

There is a remarkable class of words called 'ideophones' in many Tupian languages. Although their properties are not yet totally understood and/or described, roughly, ideophones have similarities to intransitive verbs, but their phonological, morphological, syntactic, and discourse behaviors are rather different. Ideophones are found in Karo (Ramaráma), Karitiána (Arikém), Mundurukú (Mundurukú), Xipáya (Jurúna), and Kamayurá (Tupí-Guaraní). Languages of the Awetí, Mawé, Mondé, and Tuparí branches do not have ideophones, but rather have a class of uninflected verbs.

Syntactic characteristics of Tupian languages include a basic subject-object-verb (SOV) order of clause constituents, with fronting of S or O being used as a syntactic device for emphasis or contrast. The occurrence of clause-chaining constructions, whereby a clause is structured of one main verb in the finite form plus one or more chained verbs in nonfinite or unmarked form, is common and is sometimes erroneously interpreted as serial verb constructions (Jensen, 1990). Typically, coreferential intransitive subjects receive special markings in chained clauses (although this does not characterize a switch-reference system), and transitive subjects are absent (zero-anaphora).

Evidentiality is also a widespread phenomenon in all branches of the Tupí family. Unfortunately, this is not yet fully understood and described, with the exception of Karo (Gabas, 1999) and Kamayurá (Seki, 2000). In Karo, the 11 evidentials are grouped in two categories. One grouping refers to the attitude of the speaker toward the proposition conveyed, and the other refers to the source of information. For Kamayurá, Seki (2000: 104) has described the existence of 'interjective particles' that are used to report to the attitude of the speaker toward the information conveyed. Although Seki does not explicitly analyze these particles as being evidentials, they can easily be interpreted as such.

Tupian languages also have systems of noun classification. In two branches, Mundurukú and Karo, a robust classifier system occurs. In Mundurukú, approximately 50 classifiers occur associated with the preceding noun according to their shape. Classifiers in Mundurukú also occur in concordance with other elements in the noun phrase. In Karo, a set of 11 classifiers occurs, relating to the shape (7), arrangement (2), and gender (1) of the preceding noun (the meaning of the 11th classifier remains unknown). Classifiers in Karo also occur, obligatorily, after an adjective, in concordance. Although languages of other branches do not have classifier systems per se, cognates of classifiers in Karo and Mundurukú occur lexicalized in many words throughout the family, usually the classifier for round objects, *ʔaʔ*; the classifier for concave/convex objects, *ka* or *kap*; and the classifier for flat objects, *peʔ*. This suggests that a system of noun classification already existed in the protolanguage, Proto-Tupí.

Turgot, Anne Robert Jacques (1727–1781)

D Droixhe

© 2006 Elsevier Ltd. All rights reserved.

This article is reproduced from the previous edition, volume 9, pp. 4777–4778, © 1994, Elsevier Ltd.

Born in Paris in 1727, the future *Intendant* of Limousin (1761–1774) and General Controller of Finances (1774–1776) started to discuss the fashionable question of language under the influence of Condillac (1746; *see* **Condillac, Etienne Bonnot de (1714–1780)**) and Maupertuis (1748). His commentary on the latter's *Réflexions philosophiques sur l'origine des langues et la signification des mots* was opposed, in a pre-Rousseauist way, to the idea of the invention of language by primitive reasoning like a 'philosopher.' Words evolve dynamically from metaphors to a sort of *tablature*, 'a methodical disposition of signs' which allows thinking. In the metaphors are culturally printed the various perceptions of the world; so, Turgot rejected at the same time the Cartesian primacy of ideas and the growing tendency to explain the diversity of languages by climate or national psychology. A decisive effort was made to establish the linguistic field as an object in itself.

Planning a study *On the formation of languages and general grammar*, of which some fragments are preserved, Turgot quickly shifted from genetic interrogation to 'semantic history' or 'experimental metaphysics.' He was asked to write the article *Etymologie* for Diderot's *Encyclopédie* (1756; *see* **Diderot, Denis (1713–1784)**), his main contribution to modern linguistics, which belongs to the same scientific movement as Sarmiento's *Elementos etimológicaos* (1758–1766) or Tetens's *Über die Grundsätze und den Nutzen der Etymologie* (1765–1766).

Turgot applied to this subject the Leibnizian law of continuity, with tendencies towards the principles of immediacy and proximity. An etymology must take into account the internal relationships of a given language, before it refers to exotic roots. Then, it has to reconstruct a 'chain of alterations' offering 'a succession of facts known directly or proved by credible inductions.' These alterations are not universal, but fundamentally particular and open to the most unexpected developments. 'Every language, and in every language every dialect, every nation, every century, constantly changes some letters into other letters, and resists other changes which are just as constantly adopted by neighbors.' Rask (*see* **Rask, Rasmus Kristian (1787–1832)**) recognized Turgot's epistemological innovation.

The effect of the latter in comparativism was limited by the perturbing principle of contact and borrowing, to which some lexical correspondences were readily attributed by Turgot. The prevailing concept of 'commerce' was probably not extraneous to this option, as the bourgeois ideology of the 'added value' must have influenced his insistence on the transformation of reality by words and on their poeticity.

Turgot applied to this subject the Leibnizian law of continuity, with tendencies towards the principles of immediacy and proximity. An etymology must take into account the internal relationships of a given language, before it refers to exotic roots. Then, it has to reconstruct a 'chain of alterations' offering 'a succession of facts known directly or proved by credible inductions.' These alterations are not universal, but fundamentally particular and open to the most unexpected developments. 'Every language, and in every language every dialect, every nation, every century, constantly changes some letters into other letters, and resists other changes which are just as constantly adopted by neighbors.' Rask (*see* **Rask, Rasmus Kristian (1787–1832)**) recognized Turgot's epistemological innovation.

The effect of the latter in comparativism was limited by the perturbing principle of contact and borrowing, to which some lexical correspondences were readily attributed by Turgot. The prevailing concept of 'commerce' was probably not extraneous to this option, as the bourgeois ideology of the 'added value' must have influenced his insistence on the transformation of reality by words and on their poeticity.

Between Vico and Herder (*see* **Herder, Johann Gottfried (1744–1803)**), announcing the German creativity of sign (Tetens's *Bildendes Dichtungsvermögen*), Turgot invented and spontaneously articulated several features of a change leading to romanticism.

Introduction

'The Turing Test' is the name given to any of several variations of an experiment proposed by the mathematician and computer scientist Alan M. Turing in his essay, 'Computing machinery and intelligence,' which appeared in the philosophy journal *Mind* in 1950. The Test, briefly put, is for an interrogator to decide whether a participant in a natural-language conversation is a human or a computer. The participant passes the test to the extent that it convinces the interrogator that it is human (even if it is really a computer). (For simplicity, I will usually call the one (or two) participant(s) in a Turing Test other than the interrogator *the participant*. In different versions of the Test, the participant(s) might be a male and/or female human, a computer, or perhaps some other candidate for the ascription of *intelligence*.)

The experiment, a version of a parlor game that Turing called *the imitation game*, was designed to help answer the question 'Can machines think?' by replacing that informal question (containing the vague terms *machines* and *think*) by a more precise question: Can a computer 'pass' a Turing Test? Thus, the vague terms *machines* and *think* are replaced by, respectively, the more precise notions of a digital computer (or a Turing machine) and the more precise – or at least behaviorally determinable – notion of passing the Test. (This strategy – replacing a vague, informal question that is difficult to answer with a more precise question that is easier to answer – is similar to the strategy that Turing (1936) adopted in giving his extremely influential answer to the question of what 'computable' means.)

The Imitation Game

The original 'imitation game' consists of three players: a man, a woman, and an interrogator, each in a separate room, communicating only via teletype (or what today would be considered an 'instant messaging' interface), such that none of the players can see or hear the others, thus limiting their interactions to typed (i.e., written) linguistic communication. We will consider the extent to which this is a limitation later on. The woman's task is to convince the interrogator that she is the woman; the man's task is to **imitate** a woman so as to convince the interrogator that he **is** the woman; and the interrogator's task is to determine who is which. The man wins the imitation game (i.e., 'passes' the imitation-game 'test') if he succeeds in convincing the interrogator (e.g., perhaps by deception) that he is the woman; thus, the woman succeeds (as does the interrogator) to the extent that

Between Vico and Herder (*see* **Herder, Johann Gottfried (1744–1803)**), announcing the German creativity of sign (Tetens's *Bildendes Dichtungsvermögen*), Turgot invented and spontaneously articulated several features of a change leading to romanticism.

Turing Test

Introduction

'The Turing Test' is the name given to any of several variations of an experiment proposed by the mathematician and computer scientist Alan M. Turing in his essay, 'Computing machinery and intelligence,' which appeared in the philosophy journal *Mind* in 1950. The Test, briefly put, is for an interrogator to decide whether a participant in a natural-language conversation is a human or a computer. The participant passes the test to the extent that it convinces the interrogator that it is human (even if it is really a computer). (For simplicity, I will usually call the one (or two) participant(s) in a Turing Test other than the interrogator *the participant*. In different versions of the Test, the participant(s) might be a male and/or female human, a computer, or perhaps some other candidate for the ascription of *intelligence*.)

The experiment, a version of a parlor game that Turing called *the imitation game*, was designed to help answer the question 'Can machines think?' by replacing that informal question (containing the vague terms *machines* and *think*) by a more precise question: Can a computer 'pass' a Turing Test? Thus, the vague terms *machines* and *think* are replaced by, respectively, the more precise notions of a digital computer (or a Turing machine) and the more precise – or at least behaviorally determinable – notion of passing the Test. (This strategy – replacing a vague, informal question that is difficult to answer with a more precise question that is easier to answer – is similar to the strategy that Turing (1936) adopted in giving his extremely influential answer to the question of what 'computable' means.)

The Imitation Game

The original 'imitation game' consists of three players: a man, a woman, and an interrogator, each in a separate room, communicating only via teletype (or what today would be considered an 'instant messaging' interface), such that none of the players can see or hear the others, thus limiting their interactions to typed (i.e., written) linguistic communication. We will consider the extent to which this is a limitation later on. The woman's task is to convince the interrogator that she is the woman; the man's task is to **imitate** a woman so as to convince the interrogator that he **is** the woman; and the interrogator's task is to determine who is which. The man wins the imitation game (i.e., 'passes' the imitation-game 'test') if he succeeds in convincing the interrogator (e.g., perhaps by deception) that he is the woman; thus, the woman succeeds (as does the interrogator) to the extent that

the man fails. This version of the imitation game seems to be computationally solvable: a computational study has suggested that it is possible to identify stylistically whether the author of a given text is male or female (see Argamon *et al.,* 2003) for a computational investigation of this.

The Turing Test and Its Variations

Several versions of the Turing Test may be found in Turing's essay and in subsequent literature. Turing's first version merely replaces the man in the imitation game by a computer. If the interrogator fails as often as he or she did with the imitation game, then the computer is said to have 'passed the Turing Test'. But does this mean that the computer passes the Test if it is able to convince the interrogator that it is a man who, in turn, is trying to convince the interrogator that he is the woman?

It is reasonably clear from Turing's essay that he had in mind something less convoluted. Thus, the second version of the Test replaces the man by a computer and the woman by another **man**, and so the computer's task is to convince the interrogator that it is a man (see Colby *et al.,* 1972: 202 and Shieber, 2004: 100–104 for further discussion of the gender issue).

A more gender-neutral version replaces the man by a computer and the woman by a **human** (of either sex). The computer passes this version of the Test if it convinces the interrogator that it is the human.

In modern versions of the Test, this is simplified even more, by having an interrogator and only one participant: either a computer or a human. Again, the computer 'passes' this Test if it convinces the interrogator that he or she is interacting with a human. Turing (1950) alludes to this version as a *viva voce*, i.e., an oral examination; a subject passes an oral exam by convincing the examiner that he or she 'understands' the material that he or she is being tested on.

Another variation (Stuart C. Shapiro, personal communication) depends on whether the interrogator **knows** that there is a possibility that the participant is a computer or whether the interrogator is merely being asked to judge whether the participant is intelligent (or as intelligent as a normal person).

Turing (1950: 441) also mentions a version of the Test in which the interrogator must distinguish between a digital computer and a discrete-state machine. Other variations are described later on.

Passing the Test

As a standard for deciding whether a participant has passed the Test, Turing (1950: 442) proposed that "an average interrogator will not have more than 70 per cent. [*sic*] chance of making the right identification after five minutes of questioning." Some researchers have complained that this sets the standard too low, but the actual statistical standard to be applied could easily be varied (e.g., 70% increased to 95%, 5 minutes increased to several months, etc.). Turing's prediction was "that at the end of the century [i.e., by 2000], the use of words and general educated opinion will have altered so much that one will be able to speak of machines thinking without expecting to be contradicted" (Turing, 1950: 442). (We will examine these two standards later in this essay. At the end of the century, in fact, several anthologies considered the status of Turing's prediction: Akman and Blackburn, 2000; Moor, 2000–2001; Moor, 2003; Shieber, 2004.)

The Turing Test has been likened to two, more familiar situations:

1. The two-entity version (interrogator and participant) is like the situation in which a human corresponds with a pen pal (Harnad, 1989). In real life, the human would be unlikely to doubt that the pen pal was a human. One point of the Turing test is that if the pen pal were, in fact, a computer, still the human would not question its humanity (i.e., its human level of intelligence or its human ability to think).
2. As Stuart Shieber (2004) points out, the interrogator's task is like that of someone determining whether something is 1 m long by comparing it with a standard meter; both items share the same length. Here, the interrogator is determining whether something has a certain feature (namely, a human level of intelligence) by seeing if it shares that feature with (i.e., if it can be measured against) another entity, which, by hypothesis, is a 'standard' for having that feature. And, in the case of the Turing Test, the standard is written linguistic communication (Shieber's term is 'verbal behavior').

Experiments with Real Turing-like Tests

Two early AI (artificial intelligence) programs in the areas of natural-language processing and cognitive modeling are often mentioned in connection with the Turing Test. Joseph Weizenbaum's (1966, 1967) computer program Eliza appears to converse in more or less fluent English with its user, apparently simulating a Rogerian psycho-therapist. Many anecdotes of people being fooled into thinking that they were conversing with a real human suggest that Eliza has passed a Turing-like Test. Yet Eliza's natural-language-processing techniques are mere pattern

matching using little or no grammatical knowledge (e.g., swapping pronouns such as you and me in certain patterns) – i.e., the techniques are not cognitive. Hence, Weizenbaum has claimed that Eliza is a counterexample to the Turing Test. But this has not been subject to controlled experiments.

On the other hand, Kenneth Mark Colby's computer program Parry is an Eliza-inspired program that, using more sophisticated natural-language-processing techniques than Eliza, simulates a paranoid patient. Parry has been the subject of controlled Turing-Test-like experiments (Colby *et al.,* 1972; Colby, 1981), and Colby, at least, claims that it has passed the Turing Test, having convinced human psychotherapist judges that they were conversing with a human paranoid patient. On the other hand, that is all that Parry can discuss, and so it is not clear that the sort of test that it passes is a full-fledged Turing Test.

The Loebner Prize Competition, held annually since 1991, is a Turing-like test that has offered a monetary award "for the first computer whose responses were indistinguishable from a human's. Each year an annual prize of $2000 and a bronze medal is awarded to the most human computer. The winner of the annual contest is the best entry relative to other entries that year, irrespective of how good it is in an absolute sense" (Loebner, 2003). Most of the winners have been elaborate Eliza-like programs (sometimes called *chatterbots*). However, one notable exception was David Levy's CONVERSE program (Batacharia *et al.,* 1999), which won the Loebner Prize in 1997, and which was developed by a team including at least one well-known researcher in computational linguistics (Yorick Wilks). The Loebner Competition has been critically analyzed by the computational linguist Stuart Shieber, who has argued that the Competition, unlike other competitions for professional computational linguists (e.g., the Message Understanding Conferences and the Text Retrieval Conferences), has not fostered research and development, but merely encouraged unintelligent, Eliza-like chatterbot programs whose sole goal is to fool the judges (Shieber, 1994a, 1994b; for Loebner's reply, see Loebner, 1994).

Turning the tables, some projects have used computers as 'interrogators' in a Turing-like test to unmask computer programs that attempt to convince other computer programs that they are human and hence entitled, say, to e-mail accounts. However, these tests are not based on natural-language understanding or even verbal behavior; they usually involve visual images containing distorted words that only humans can read (Ahn *et al.,* 2004). One formal investigation that replaces the interrogator with a Turing machine claims to show that no computer can be a perfect interrogator in the standard Turing Test (Sato and Ikegami, 2004). And there have been other investigations of the formal, logical, and computational structure of the Turing Test (e.g., Bradford and Wollowski, 1994; Shieber, 2005).

What Must a Computer Be Able to Do in Order to Pass the Turing Test?

A significant feature of the Test is the central role of language. To pass the Test, a participant must be able to communicate in the written natural language of the interrogator to such an extent that the interrogator cannot distinguish its linguistic behavior from that of a human using that language. (To simplify matters, we will assume that all participants speak that language equally well.)

This feature echoes a historical antecedent to the Turing Test: in his *Discourse on method* (1637: Part V), the philosopher René Descartes argued that there was a test that could show that a machine that looked and behaved like a human was not a real human, namely, that even if it could use language in certain appropriate, responsive ways (e.g., to "ask what we wish to say to it" if "touched in a particular part," or to "exclaim that it is being hurt" if touched somewhere else), it could not "arrange its speech . . . in order to reply appropriately to everything that may be said in its presence" (Descartes, 1637/1970: 116). There are two issues to consider: (1) Is linguistic ability a reasonable replacement for the informal notions of 'thinking' or 'intelligence'? (2) Must the test be limited to linguistic ability?

Is Written Linguistic Behavior a Reasonable Replacement for 'Cognition'?

'Thinking' is a vague term, and 'intelligence' is not necessarily, or even probably, intended in the sense of the IQ-test notion of intelligence, but merely as a convenient synonym for 'cognition'. Therefore, we will use the latter term, which is less controversial.

To approach an answer to the question of whether written linguistic behavior can replace 'cognition', we can look at what Turing thought the computer might have to be able to do. In his examples of the computer's behavior and in his replies to a series of potential objections, Turing suggests that the computer might have to do the following (kinds of) things:

- Answer questions about its physical appearance and abilities.
- Answer questions about its personality and experiences.
- Write and discuss a poem on a given topic.

- Do arithmetic.
- Solve chess problems.
- Have access to, and be able to use, commonsense information about the seasons, Christmas, familiar fictional characters, etc. (This is sometimes called world knowledge.)
- Learn.

For Turing, the last of these was the most important. Presumably, this learning would have to come from reading, not from doing, although Turing also suggests that the machine might have other "experience[s], not to be described as education." In any case, Turing seems to have been willing to restrict the Test-passing capabilities of the machine to "all purely intellectual fields," which, presumably, manifest themselves through language.

Insofar as ordinary cognition is surely involved in these sorts of activities, being able to do them does seem to be a reasonable test of human-level cognition. Surely, if a machine could do such things, an interrogator would be justified in being unable to distinguish between it and a human who could do them equally well. Hence (perhaps), the interrogator would be justified in concluding that the participant had cognition. Turing, however, does not say that the interrogator needs to draw the conclusion that the participant really has cognition (i.e., really can do these things); perhaps this is why he wrote that "the use of words and general educated opinion will have altered so much that one will be able to speak of machines thinking without expecting to be contradicted."

Thus, a computer must have at least the following two capacities to pass a Turing Test: (1) the ability to understand and generate natural language; (2) lots of world knowledge. Let us consider each of these.

Understanding Natural Language What counts as 'understanding' (including generating) natural language? Turing apparently thought that it simply meant behaving in such a way that the interrogator **believes** that the participant understands the language, i.e., that the interrogator **attributes** natural-language understanding to the participant (cf. Dennett's (1968) "intentional stance"). Cognitivists hold that it means something more than mere behavior. Perhaps any entity that exhibits such behavior must have the further capacity to be able to parse linguistic input, construct a (mental) representation of it, integrate or assimilate it into 'background knowledge', determine an appropriate linguistic response, and formulate and express that response in a grammatical utterance. Or **understanding** natural language might mean something even more than certain behavior together with this natural-language-**processing** capacity: Perhaps the entity must have "intrinsic intentionality" or consciousness (Searle, 1980).

World Knowledge Understanding natural language is probably not something that can be done merely on the basis of linguistic knowledge (e.g., knowledge of a grammar and lexicon). It probably requires much world knowledge – not only semantic and pragmatic knowledge, but also something like what the educational reformer E. D. Hirsch (1987) calls 'cultural literacy' or what the AI researcher Douglas B. Lenat (1995) calls 'commonsense knowledge', i.e., lots of facts about the world, and perhaps also some specialized domain knowledge (e.g., knowledge of how to play chess).

The computational linguist Terry Winograd argued for the claim that natural-language understanding requires such knowledge: consider these two sentences, which differ in only one word: (a) "The city councilors refused the demonstrators a permit because they advocated violence" and (b) "The city councilors refused the demonstrators a permit because they feared violence." Arguably, it is 'world knowledge' or 'commonsense knowledge' about the roles of city councilors and demonstrators, as well as semantic knowledge about the meanings of the words *advocated* and *feared*, that aids in determining that the word *they* refers to the demonstrators in (a) but to the city councilors in (b).

Moreover, someone reading *The Diary of Anne Frank* who does not understand the word *Gestapo* might be told that it was Hitler's secret police, but if the reader does not know who Hitler was, this will not be of much help. The reader needs to know that Hitler was the Nazi dictator of Germany during World War II, who the Nazis were, where Germany is, what World War II was, etc.

Is Written Linguistic Communication a Limitation?

Must the test be limited to linguistic behavior? After all, cognition in general is usually taken to consist of more than just linguistic ability; e.g., it includes learning, perception, reasoning, memory, planning (and acting on those plans), etc. In the original imitation game, the restriction to linguistic interrogation eliminated the need to deal with the physical make-up of the participants. Limiting the interrogation to linguistic communication does not seem debilitating: surely the sorts of conversations that Turing suggested cover a wide range of intellectual activities – enough to convince an interrogator of the

participant's cognition (or, more precisely, the participant's cognitive-behavioral indistinguishability from a human).

Linguistic ability by itself is surely a mark of cognition. Moreover, it may be that linguistic ability is the essential core of the kind of cognition that is in question, in the sense that any entity that had such linguistic ability is highly likely to have – or require – most other kinds of cognition (Rapaport, 1988; Harnad, 1989; Rey, 2002). Not only does natural-language understanding require world knowledge, but it is arguably the case that natural-language understanding is 'AI-complete'; i.e., 'solving' the natural-language-understanding problem may require solving all other problems in AI (artificial intelligence). If so, then, insofar as passing the Turing Test requires natural-language understanding, it would be a sufficient condition of cognition. In any case, the psychologist Stevan Harnad (1989) has proposed a Total Turing Test variation that extends the Test to allow for demonstrations of perception, action, and other sorts of non-linguistic cognition (or cognitive indistinguishability from humans).

If passing the Turing Test requires, not merely the ability to fool or (statistically) convince an interrogator that he or she is conversing with a human (or at least with an entity with human-level cognition), but actual, human-level linguistic abilities, then what kinds of abilities are required? Research in AI and computational linguistics since the mid-1950s suggests that any natural-language understander – including a Turing-Test-passing program – must be able (at least) to:

1. take coherent discourse (as opposed to isolated sentences) as input
2. understand ungrammatical input
3. make inferences and revise beliefs
4. make plans (for speech acts, to ask and answer questions, and to initiate conversation)
5. understand plans (including the speech acts of all interlocutors in the conversation)
6. construct user models (i.e., 'theories of mind', or psychological theories, of all interlocutors)
7. learn about the world and about language, and do this in part via a natural-language interaction
8. have background (or 'world', or 'commonsense') knowledge
9. remember what it heard, learned, inferred, and revised.

Arguably, any entity having these abilities could be said to be able to understand language or, more generally, to be cognitive, or to think. The open research question is whether **computational** theories of these cognitive abilities can be developed.

What Does Passing the Turing Test Mean?

Does Passing the Turing Test Demonstrate Real Cognition or Only the Appearance of Cognition?

Is a machine that **appears** to understand natural language or to have cognition **really** understanding natural language; does it really have cognition? Perhaps the early-to-mid-20th-century behavioral bias made it seem reasonable to Turing that his test answers this question in the only way possible. But the modern late-20th-to-early-21st-century cognitive bias has kept the question open.

One position is that if the output of the machine is not produced by 'the same' methods that humans use, then although its external behavior might be similar to a human's, its internal mechanism is not and, hence, it is not really doing them. Another position is that anything that is capable of these complex sorts of linguistic behavior is indeed communicating in language (at least, no less than a human is) and not merely appearing to, no matter what internal mechanism produces the output. That is, it is not merely simulating the use of language; rather, at least in the case of language use (and other cognitive phenomena), this sort of simulation **is** the real thing (Rapaport, 1988).

Another line of argument, however, suggests that even in the case in which it is felt that the appearance is not reality, it is near enough so as not to matter. Some support for this is given by Turing's statement "that at the end of the century **the use of words** and **general educated opinion** will have altered so much that one will be able to speak of machines thinking without expecting to be contradicted." One way that this might come about is if "the use of words" were to change, e.g., the meaning of *think* might be extended metaphorically to cover both machines and humans. Enlarging the scope of meaning of a word is something that has happened many times before: "To fly" was once something that only birds and bats were said to do; now, airplanes, helicopters, space shuttles, and their human riders are all said to fly. A 'computer' was once a **human** whose job was to carry out complex or lengthy mathematical calculations; now, it is a **machine** that does what those humans once did. Such semantic enlargements can come about by metaphorical extension: perhaps planes do not literally fly (in the bird-sense), just as philosophers do not literally shoot down an opponent's argument, but we eventually come to apply the metaphor so often that it becomes an unquestioningly acceptable – even unavoidable – predication.

In addition to "the use of words" changing, it is also possible for "general educated opinion" about the nature of cognition to change, perhaps as a result

of progress in AI, philosophical analysis, or psychological research, e.g., the meaning of the word *think* might be abstracted to an essence that allows it to be predicated of both AI-programmed computers and humans (not to mention other animals). Our current theoretical understanding of heavier-than-air flight encompasses both bird flight and airplane flight. And our current theoretical understanding of computation – due, in fact, to Turing (1936) – has its foundation in an analysis of what human computers do. Extending this idea, progress in AI and cognitive science could cause us to have a better understanding of cognition in such a way that the new understanding applies to both humans and machines.

Is Passing the Turing Test a Sufficient Demonstration of Cognition?

In what sense does passing the Turing Test **replace** the vague notion of 'thinking'? Logically, there are two possibilities: it is a necessary condition, or it is a sufficient condition (or both). To say that passing the Turing Test is a **necessary** condition of 'thinking' is to mean that if something thinks, then it can pass the Turing Test. It might, of course, be the case that something can think but fails the Test, perhaps because the interrogator is not up to par or because the thinking agent simply is having an 'off day'. But, presumably, under normal circumstances, a real cognitive agent that takes the Test will pass it.

More controversial is the proposition that passing the Turing Test is a **sufficient** condition of 'thinking'. To say this is to mean that if something passes the Test, then it 'thinks'. Several objections to the Turing Test take the form of showing that it is not a sufficient condition for thinking.

The 'Aunt Bertha' Table-Lookup Objection One, due to the philosopher Ned Block (1981), considers a computer program that stores a finite, but extremely large, number of possible conversations – all the one-hour conversations that the programmer's 'Aunt Bertha' might possibly have during her entire life, on any subject whatever. Such a program would, presumably, pass the Test, yet would not normally be considered to 'think'. The point is that the methods whereby the responses are produced are behaviorally, but not psychologically, plausible. Thus, we have a case of something that passes the Test but does not think, which is a counterexample to the test's sufficiency. Thinking, according to this objection, is not merely a matter of behavior, but also a matter of how that behavior is produced, and certain ways of producing it are not suitably cognitive (such as memorizing a large lookup table), whereas certain others might be (such as requiring reasoning; cf. Shannon and McCarthy, 1956).

One possible response is to deny the possibility of such a 'pre-compiled' lookup table (e.g., such a system could not learn new words). To this objection it can be replied that there is only a finite (albeit astronomically large) number of possible words, all of which could be pre-compiled. On behalf of the Test, another response to Block's objection is to admit this, but to point out that the Test still provides considerable evidence supportive of a claim to cognition and, in the absence of any ability to know how the cognitive behavior was produced (as in the pen pal case), that might be all the evidence one could possibly have.

The Chinese-Room Objection Perhaps the most well-known objection to the Test's sufficiency is the philosopher John Searle's (1980) Chinese-Room Argument. Here, a human who knows no Chinese is placed in a room with an instruction book that tells him how to manipulate certain symbols that are input to him in the room, and then how to output other symbols on the basis of these manipulations. The interrogator is a native speaker of Chinese who inputs questions written in Chinese characters and reads the output from the room. By hypothesis, the interrogator judges that the entity with which he is fluently conversing understands Chinese, whereas, again by hypothesis, the human in the room in fact knows no Chinese and is merely manipulating marks that are 'meaningless' to him. Thus, we seem to have a case in which something does not have a certain sort of cognition (in this case, understanding natural language) yet passes the Turing Test (and, moreover, via 'reasoning' as opposed to 'memorization').

One response to Searle's proposed counterexample is to object that the solo human is not the Test-taker; rather, the Test is being taken – and passed – by the system consisting of the human combined with the instruction book, and it is possible that that **system** does understand Chinese even though its **parts** do not. In any case, denying that the **system** understands Chinese is not the same as denying that the **human** in the room understands Chinese.

This 'systems reply' is often supplemented by a 'robot reply', a version of the Total Turing Test in which the participant memorizes the instruction book and is endowed with other kinds of cognition, such as those involving sensors (e.g., perception) and effectors (e.g., acting). Finally, as in the AI-complete situation, perhaps a suitably rich sort of symbol manipulation (combining linguistically derived concepts with perceptually derived concepts) could provide the

apparently missing semantic component (Rapaport, 2000).

Is Cognition Subjective? Both Block's and Searle's objections also raise the issue of whether cognition (or natural-language understanding) is a subjective phenomenon: a participant passes a Turing Test **with respect to a given interrogator.** Thus, a given lookup table might not work for a given interrogator, and different interrogators might disagree on whether a participant in a Chinese Room demonstrates understanding.

Is Cognitive Behavior Really Cognition?

A participant will either pass the Turing Test or not. If **no** computer ever passes it – that is, if only humans (or other entities independently judged to be capable of cognition, such as extraterrestrials) pass it – then the Test succeeds in the sense that it offers a (behavioral) mark of (human) cognition. If, on the other hand, a computer **does** pass it, that could be for two reasons: either it is **really** cognitive (and able to **convince** the interrogator of this), or else it is not but only **appears** to be.

One way of phrasing the fundamental problem posed by the Turing Test is whether mere cognitive behavior **is** real cognition. There are three possibilities: (1) Real cognition might be 'mere' input-output behavior (statistical correlation). (2) Or real cognition might be input-output behavior **plus** any intervening process (including the 'Aunt Bertha' kinds of table-lookup processes or Eliza-like natural-language-processing tricks). (3) Or real cognition might be input-output behavior with an intervening process **of a 'cognitive' kind**, such as a reasoning process, a symbolic computational process, a connectionist computational process, or a 'dynamic systems' process, implementing some psychological theory.

The Turing Test does not seem to distinguish among these three possibilities. Should it, i.e., is it only external behavior that counts as cognition, or is the internal process (if any) important, too (as Shannon and McCarthy, 1956 suggested)? Consider a 'magical' natural-language-processing machine: a pure input-output machine that takes natural language input (from the interrogator) and 'magically' yields (appropriate) natural-language output (i.e., a 'function machine' with no internal processes). Suppose this magical machine passes a Turing Test. Is it cognitive? Turing might have argued that it was, even though we could not know why or how it managed to understand natural language (after all, it's magic!). On the other hand, although we know that our brain is a non-magical natural-language processor, we are not yet at the stage where we can say with certainty that we know why or how **it** manages to understand natural language.

Thus, the fundamental problem of the Turing Test is the classic problem of intension vs. extension: Is the **way** in which a result is obtained or an act is performed (i.e., the result or act viewed intensionally) more important than the **result** itself (i.e., the result or act viewed extensionally)? From the perspective of linguistics, is the ability to respond to stimuli with 'fluent' verbal behavior that is indistinguishable from 'normal' human verbal behavior different from a 'deeper', 'cognitive' ability of 'understanding language'? (This is nearly the debate between B. F. Skinner's theory of verbal behavior and Noam Chomsky's theories of grammar.)

Thus, there are two possibilities as to why a participant might pass a Turing Test: its cognitive behavior is (merely) extensionally equivalent to (real, human) cognition, or its cognitive behavior is (also) intensionally equivalent to real (human) cognition. Should the first possibility vitiate the Test? Suppose that the interrogator (an external observer) takes the 'intentional stance' and ascribes cognition to the participant. It does not follow that the participant is **not** really (intensionally) cognitive. After all, one reason that ascribing an internal, intensional cognitive state or process might be the best explanation for an entity's behavior is that the entity really produced its behavior via that process.

Consider the Aunt Bertha memorization machine. Suppose that the table lookups can be done in real time. We seem to be faced with two choices: assert that it is a counterexample to the Turing Test or accept that the Aunt Bertha machine really is cognitive (and not merely **behaving** cognitively). On the side of real cognition, we could argue that the Aunt Bertha machine would not work – that only a real cognitive agent could pass the Turing Test. The Chinese-Room Argument would **not** be a counterexample in this case, because the Chinese-Room system consisting of the human together with the instruction book might only pass if the instruction book were AI-complete, containing a full computational cognitive theory. To assert that it could not contain such a theory is to go beyond the empirical evidence, especially because we do not have that evidence yet.

Or, also on the side of real cognition, we could bite the bullet and say that the Aunt Bertha machine **is** cognitive **despite** being a mere lookup table, i.e., that appropriate lookup tables are just one way of being cognitive (cf. Putnam's (1960) Turing-machine

lookup-table analogy to the human mind). In other words, the **appearance** of cognition **is** real cognition; i.e., the external ascription of cognition is all that matters (as in the pen pal case). Arguably, our ordinary notion of 'understanding' applies to an omniscient deity that would never have to draw inferences or in any way 'process' information. Thus, if table lookup is not cognition, then such omniscience would not be cognitive, which seems to violate our pre-theoretical intuitions.

Consider an analogy: a Turing Test for seeing. Under what conditions would it be fair to say that an external observer can determine whether an entity sees? Is mere 'seeing behavior' enough?, e.g., is it enough that the entity reacts appropriately to visual stimuli whether or not it has any internal representation of them? Plants not only respond tropistically to light, but there is even some evidence that they can sense the presence of distal stimuli by means of light reflection. So, do plants see? Probably not, in the sense that they probably have no internal representation of the external stimuli – but can that be determined behaviorally? Consider 'blindsight': there is evidence that some blind humans can respond appropriately to visual stimuli. Do they see (despite their protestations that they cannot)? This case is especially puzzling, because it is conceivable that such blindsighted humans have internal representations that they use in processing the external stimuli, yet they are not aware of them.

Conclusion

Turing hoped that his Test would replace the question, 'Can machines think?' It has not – in large part because of disagreement over whether it is an appropriate replacement. Any formal idea that is proposed to replace an informal one is bound to suffer from this problem, for the formal idea will always include some feature that the informal one appears to exclude, and vice versa. In the case of the Turing Test, this has given rise to the debate over its sufficiency for thinking and for cognition in general. Nevertheless, more than 50 years after its appearance, the Turing Test continues to help focus debate on issues concerning the relation of cognition to computation.

Turing, Alan Mathison (1912–1954)

B Sypniewski, Rowan University, Camden, NJ, USA

© 2006 Elsevier Ltd. All rights reserved.

Alan Turing (1912–1954), one of the most important logicians and mathematicians of the 20th century, developed the basic theory for computer science and participated in the breaking of the German secret codes during World War II. Turing's contributions to linguistics usually go unnoticed. As an abstract thinker, his achievements crossed disciplinary boundaries.

In 1937, Turing published a paper usually referred to by its shortened title, 'Computable numbers,' in which he described what is now known as a Turing machine. A Turing machine is an abstract machine that executes a program (a set of instructions) one step at a time. In theory, a universal Turing machine can compute anything that is computable. The Turing machine is the abstract basis for modern digital computers.

In 1950, he published another important paper, 'Computing machinery and intelligence,' which raised the question of whether a machine, specifically a digital computer, could think. The paper described what has come to be known as the 'Turing test,' in which an interrogator questions a hidden human and computer. All questions and answers are communicated by typewritten message. The interrogator's job is to distinguish between the computer and the human solely on the basis of the answers. One player tries to deceive the interrogator; the other player tries to help the interrogator. Turing's argument was that if the computer successfully played what he called the 'Imitation Game,' it could be said to think, since it effectively mimicked a human being.

A grammar may be considered a Turing machine. Generative grammar is claimed to be a method of generating 'correct' and only 'correct' sentences in a language. The Turing test is a test of intelligence that equates intelligence with language use. While Turing held out high hopes for successfully programming a computer to pass his test (Turing test contests have been held, and at least one computer is claimed to have passed), no one has yet shown that language use is computable in the mathematical sense. Turing showed that if intelligence equates with some level of language use, language use cannot be limited to grammar. Taking his two great accomplishments together, we can say that even if grammar is shown to be a universal Turing machine, simply creating 'correct' sentences in a language is insufficient to pass the Turing test. Turing's achievements question whether the focus of linguistics should be restricted to grammar.

An interesting development in Turing's thoughts occurred between his two great papers. A Turing machine is very simple and has the ability only to react. In the last section of his 1950 paper, Turing no longer talked about a machine that is programmed but about one that learns, perhaps by a mechanism akin to natural selection. In between his papers, Turing helped to create Britain's first computer and had daily experience with it. Turing's theoretical computers responded to conversations, not equations.

Turkey: Language Situation

A Göksel, Boğaziçi University, Istanbul, Turkey

© 2006 Elsevier Ltd. All rights reserved.

The official language of the Republic of Turkey is Turkish (Altaic/Turkic/Southwestern). It is estimated to be the first language of 80–85% of the population of 70 million people and to be spoken by native or near-native fluency by the majority of the rest of the population.

In the rest of this article, the figures given for the number of speakers of each language reflect rough estimates of first language users including bilinguals and are based on Andrews (1989), Grimes (2000), Şener (2004), and personal communication. For most of the languages with less than 30 000 speakers, the population is over 50 years of age.

Next to Turkish, the language with the largest number of speakers is Kurmanji (Indo-European/Western Indo-Iranian; 10–12 million people) followed by Zaza (Zaza-Gorani; Indo-European; 1 million people), Arabic (Afroasiatic; 1 million people), and Azerbaijani (Altaic; 500 000 people).

There are native speakers of a few dozen other languages in Turkey. These languages are spoken by the various Muslim, Christian, and Jewish communities that Turkey inherited from the Ottoman Empire in 1923 (Turks, Greeks, Armenians, Jews, Kurds, Gypsies, Tatars, Turkomans, Azerbaijanis, Albanians, Arabs, Aramaens, Muslims from the Caucasus and the Balkans, and others). More recently, immigrants, asylum seekers, and refugees from Iraq, Iran, Afghanistan, the central Asian Turkic countries, east Africa, and Nigeria have been coming into Turkey. There are no official figures for the numbers of speakers of these languages, as language use has not been surveyed in censuses since 1965.

Language has been the centerpiece of nation-building programs since the end of the 19th century. Turkish was proclaimed as the official language of the Ottoman Empire in the constitution of 1876 and became part of the curriculum in all schools in 1894 (Sadoğlu, 2003). The unofficial but sanctioned multilingualism (in schools and in the press) of the Ottoman period gradually gave way to the promotion of Turkish and reached a climax after the Republic was formed. In the 1930s, campaigns were launched to create a unified national identity through the usage of Turkish, which, at times, took the form of coercion (Çağaptay, 2002). The present constitution (1981, articles 3/1 and 42) designates Turkish as the "language of the Turkish State" and the only language that can be taught as the "mother tongue," except for those covered under international treaties, such as the Lausanne Treaty, 1923, articles 40–41, which in practice applies only to Armenian (Indo-European; 50 000 people) and Greek (Indo-European; a few thousand people). These languages, as well as Ladino (Indo-European, Judeo-Spanish; unknown number of speakers and designated as seriously endangered by the *UNESCO red book on endangered languages*), are also used in the print media.

Although the Lausanne Treaty of 1923 grants every Turkish citizen the freedom to use his or her language in the press and in open meetings (article 39/4; Aydın, 2002), this freedom has been put into practice only very recently; formerly, such language usage would often result in prosecution. In June, 2004, the Turkish Radio and Television Corporation started broadcasting half-hour programs in Kurmanji, Zaza, Circassian/Adyghe (Caucasian, 50 000 speakers), Bosnian (Indo-European; 20 000 speakers), and Arabic. Some broadcasts in Turkish are accompanied by signed Turkish, which is distinct from Turkish Sign Language (unknown number of users) that is used natively by members of the deaf community. Oralism has been the medium in schools for the deaf since the implementation of a 1953 regulation of the Ministry of National Education.

Also spoken are the following languages:

- *Turkic* (Altaic): Uzbek (a few thousand speakers), Turkmen, Uyghur, Kumyk (a few hundred speakers), Tatar, Karachay-Balkar (unknown number of speakers), and these languages designated as

Turkic Languages

L Johanson, Universität Mainz, Mainz, Germany

© 2006 Elsevier Ltd. All rights reserved.

Development and Classification

The Turkic language family was first attested in 8th century inscriptions. Turkic-speaking groups first appeared in the Inner Eurasian steppes, from where they moved to Central Asia, Eastern Europe, the Middle East, Siberia, etc. Because of their high mobility, Turkic expanded over a huge area.

The Proto-Turkic network of varieties was dissolved by an early split of Oghur or Bulgar Turkic. Its modern representative, Chuvash, a descendant of Volga Bulgar, differs from Common Turkic by specific phonetic representations, e.g., *r* and *l* instead of *z* and *š* in words such as *śĕr* 'hundred' and *śul* 'year' (Turkish *yüz* 'hundred,' *yaş* 'age'). A second split is represented by Khalaj, which retains a reflex of Proto-Turkic **p-* as *h-*, e.g., *hadaq* 'foot.' Dialect splitting has led to further differentiation of Common Turkic. There is no mutual intelligibility throughout the family today. The following division combines the current areal distribution with genealogical and typological features.

1. The Southwestern or Oghuz branch contains a western subgroup comprising Turkish, Gagauz, and Azerbaijanian (Azerbaijani, Northern and Azerbaijani, Southern), a southern subgroup comprising dialects of southern Iran and Afghanistan, and an eastern subgroup comprising Turkmen and Khorasan Turkic.
2. The Northwestern or Kipchak branch has a western subgroup comprising Kumyk, Karachay-Balkar, Crimean Tatar, and Karaim, a northern subgroup comprising Tatar and Bashkir, and a southern subgroup comprising Kazakh, Karakalpak, Kipchak Uzbek, Nogai, and Kirghiz (of different origin, but strongly influenced by Kazakh).
3. The Southeastern or Uyghur-Karluk branch has a western Uzbek subgroup and and eastern Uyghur subgroup.

seriously endangered by the *UNESCO red book on endangered languages:* Gagauz (Moldovan), Crimean Tatar, Noghay (Nogai), and West-Siberian Tatar
- *Caucasian*: Laz (a few hundred thousand speakers), Georgian (30 000 speakers), Abkhaz (10 000 speakers), Chechen-Ingush, Avar, Lak, Lezghian (it is unclear whether this is still spoken)
- *Indo-European*: Bulgarian, Domari, Albanian, French (a few thousand speakers each), Ossetian (a few hundred speakers), German (a few dozen speakers), Polish (a few dozen speakers), Ukranian (it is unclear whether this is still spoken), and these languages designated as seriously endangered by the *UNESCO red book on endangered languages*: Romani (20 000–30 000 speakers) and Yiddish (a few dozen speakers)
- *Neo-Aramaic* (Afroasiatic): Tūrōyo and Sūrit (a few thousand speakers each)
- *Languages spoken by recent immigrants, refugees, and asylum seekers*: Afroasiatic languages: Amharic, Somali, and Tigrigna; Niger-Congo: Lingala, Swahili, and various languages spoken in Nigeria; Indo-European: Russian and Farsi; and Altaic: Kazakh and Kirghiz (hundreds of thousands of speakers)
- *Foreign languages taught in secondary schools*: English, French, German, and Italian

Development and Classification

The Turkic language family was first attested in 8th century inscriptions. Turkic-speaking groups first appeared in the Inner Eurasian steppes, from where they moved to Central Asia, Eastern Europe, the Middle East, Siberia, etc. Because of their high mobility, Turkic expanded over a huge area.

The Proto-Turkic network of varieties was dissolved by an early split of Oghur or Bulgar Turkic. Its modern representative, Chuvash, a descendant of Volga Bulgar, differs from Common Turkic by specific phonetic representations, e.g., *r* and *l* instead of *z* and *š* in words such as *śĕr* 'hundred' and *śul* 'year' (Turkish *yüz* 'hundred,' *yaş* 'age'). A second split is represented by Khalaj, which retains a reflex of Proto-Turkic **p-* as *h-*, e.g., *hadaq* 'foot.' Dialect splitting has led to further differentiation of Common Turkic. There is no mutual intelligibility throughout the family today. The following division combines the current areal distribution with genealogical and typological features.

1. The Southwestern or Oghuz branch contains a western subgroup comprising Turkish, Gagauz, and Azerbaijanian (Azerbaijani, Northern and Azerbaijani, Southern), a southern subgroup comprising dialects of southern Iran and Afghanistan, and an eastern subgroup comprising Turkmen and Khorasan Turkic.
2. The Northwestern or Kipchak branch has a western subgroup comprising Kumyk, Karachay-Balkar, Crimean Tatar, and Karaim, a northern subgroup comprising Tatar and Bashkir, and a southern subgroup comprising Kazakh, Karakalpak, Kipchak Uzbek, Nogai, and Kirghiz (of different origin, but strongly influenced by Kazakh).
3. The Southeastern or Uyghur-Karluk branch has a western Uzbek subgroup and and eastern Uyghur subgroup.

4. The Northeastern or Siberian branch has a southern heterogeneous subgroup comprising Sayan Turkic (Tuvan, Tofan), Abakan (Yenisei) Turkic (Khakas, Shor), Chulym Turkic, Altai Turkic (Altai, Northern and Southern), and a northern subgroup comprising Yakut (Sakha) and Dolgan.
5. Chuvash is geographically situated in the northwestern area (Volga region).
6. Khalaj is geographically situated in the southwestern area (central Iran).

Deviant languages in China are Salar, of Oghuz origin, Yellow Uyghur (Yugur, West) and Fu-yü (Manchuria), both of south Siberian origin.

One traditional classificatory criterion is the final consonant of the word for 'nine.' Its representation as *r* in Chuvash *tăxxăr* separates Oghur from Common Turkic (Turkish *dokuz*). The intervocalic consonant in the word for 'foot' divides most Northeastern languages, Chuvash, Khalaj, etc. from the rest, which exihibits *-y-* (Turkish *ayak*), e.g., Tuvan *adaq*, Khakas *azax*, Chuvash *ura*. Oghuz Turkic differs from the rest by loss of suffix-initial velars, e.g., *qal-an* [remain-PART] instead of *qal-γan* [remain-PART] 'remaining.' Final *-G* is devoiced in the Southeast (Uyghur *taγ-liq* [mountain-DER] 'mountainous'), preserved in southern Siberia (Tuvan *daγ-lïγ* [mountain-DER]), and lost elsewhere (Turkish *dağ-lı* [mountain-DER]).

Most older linguistic stages are insufficently known. Written sources, where available, provide no direct information on spoken varieties. Early Oghuz and Bulgar (East Europe, 6th–7th centuries) are unknown. There are no texts in the language of the Khazars (7th–10th centuries). Pecheneg and Kuman, predecessors of West Kipchak, are only known from loanwords, titles, and names.

Written Varieties

Turkic literary varieties have emerged in various cultural centers. Many older Turkic empires, however, used foreign languages for administration (Sogdian, Persian). Muslim Turks often used Persian for poetry, and Arabic for religious and scientific writing. Russian has played an important role for many groups. The following main stages of written Turkic may be distinguished.

1. An older pre-Islamic East Old Turkic period (8th century–), is represented in inscriptions, manuscripts, and block prints. East Old Turkic proper is documented in stone inscriptions (Orkhon Valley), which celebrate the rulers of the Second Eastern Türk Empire, in other inscriptions found in Mongolia and the Yenisei and Talas valleys, and also in a few manuscripts. The Old Kirghiz inscriptions are of this type. Old Uyghur is first recorded in the period of Uyghur rule over the Eastern Empire. Early Old Uyghur is attested in runiform inscriptions and manuscripts. From the 10th century on, Old Uyghur became the medium of a flourishing literary culture in the Tienshan-Tarim area, attested in texts of Buddhist, Manichaean, and Nestorian content.
2. A middle Turkic period comprises various early Islamic varieties.

   The first East Turkic written language, Karakhanid (11th century–), developed in Kashgar, is close to Old Uyghur but lexically influenced by Arabic and Persian. Maḥmūd of Kashgar provides information (1073) on Karakhanid and other contemporary Turkic varieties.

   Khorezmian Turkic, used in the 13th–14th centuries in the Golden Horde and Mamluk Egypt, is based on the older languages but contains Oghuz and Kipchak elements.

   This tradition is continued in Chaghatay (15th century–). Early Chaghatay contains regional elements of the Timurid area. Later, Chaghatay became the dominant written language of Central Asia, eventually conquering an immense area of validity and developing regional varieties.

   The first West Turkic written language is Volga Bulgar, insufficiently known from epitaphs of the 13th and 14th centuries. Information on early Kipchak Turkic is given in the Codex Cumanicus, compiled by Christians, and in dictionaries and grammars written in Mamluk Egypt and Syria.

   Oghuz Turkic is first represented by Old Anatolian Turkish (13th century–), which was a subordinate written medium until the end of Seljuk rule. Old Ottoman is the initial stage of Ottoman, which begins with the foundation of the Ottoman Empire in 1307. In Azerbaijan a literary language developed from the 15th century on.
3. A premodern period (16th century–) begins with the development of regionally influenced written languages. Middle and Late Ottoman became the leading written language with an abundantly rich literature. Chaghatay continued to play a major role and remained the literary language of all non-Oghuz Muslim Turks until a century ago.
4. A modern period begins in the second half of the 19th century with the formation of regional written languages. The political division of the Turkic-speaking world in the 20th century and the language policies pursued in the Soviet Union, Turkey, China, and Iran had dramatic effects that increasingly obstructed transregional linguistic contacts. A dozen 'national' languages with a narrow radius of validity emerged. In Turkey,

Ottoman was replaced by modern Turkish. The social importance of many Turkic languages was very limited. After the recent political developments, their significance is rapidly increasing, but the varieties spoken in Iran, Afghanistan, Iraq, etc., still have poor possibilities to develop.

Various scripts and script systems have been applied to Turkic. A specific runiform script was created for Old East Turkic. Most Old Uyghur texts are written in Uyghur script, originating in the Near East and later taken over by Mongols and Manchus. It is similar to the Sogdian script, which is also used in Buddhist texts. A few Buddhist manuscripts are written in Brahmi script, Manichaean texts in Manichaean script, and Nestorian texts in Syriac script. Arabic script was used for the languages of the Islamic era (still used in China for Uyghur and Kazakh). A unified Roman-based script was introduced for several languages in the early Soviet period, but later replaced by different Cyrillic-based scripts. A Roman-based alphabet was introduced in Turkey in 1923. Most of the newly established Turkic republics have introduced or are introducing Roman-based scripts.

Contacts

The massive displacements of Turkic-speaking groups throughout their history have led to various phenomena induced by contacts with Iranian, Slavic, Mongolic, Uralic, etc. Speakers of Turkic have copied lexical, phonetic, morphological, and syntactic elements, whereas non-Turkic (e.g., Iranian, Greek, Finno-Ugric, Samoyedic, Yeniseian, Tungusic) groups shifting to Turkic have exerted substrate influence by copying native elements into their new varieties. Languages such as Chuvash, Yakut, Salar, Yellow Uyghur, Khalaj, Karaim, and Fu-yü have long developed in isolation from their relatives, preserving old features and acquiring new ones in their environments. Long and intense interaction with Iranian in Central Asia, Iran, Afghanistan, etc., has led to profound convergence phenomena. Massive foreign influence has sometimes caused considerable typological deviations, e.g., drastic structural changes in Karaim and Gagauz under Slavic impact.

Most written languages have been strongly influenced by Persian and Arabic. In Chaghatay (Chagatai) and Ottoman, lexical borrowing contributed to a remarkable richness of the vocabularies, whereas grammar was much less affected. The overload of Persian and Arabic in Ottoman led to strong puristic efforts in the 20th century to create a so-called Pure Turkish.

Internal convergence processes have resulted in leveling of languages of the central area. Several Turkic koinés have been used as transregional codes for trade and intergroup communication, e.g., Azerbaijanian in Iran and the Caucasus region.

Linguistic Features

Despite their huge area of distribution, Turkic languages share essential phonological, morphological, and syntactic features.

They have a synthetic word structure with numerous highly applicable derivational and grammatical suffixes, and a juxtaposing technique with clear-cut morpheme boundaries and predictable allomorphs. These agglutinative principles yield considerable morphological regularity and transparency. Exceptions include traces of vowel gradation in the pronominal declination, e.g., Turkish *ben* 'I,' *ban-a* [I-DAT] 'to me.' The agglutinative structure is partly deranged in languages of the northeast and southeast. Some languages, e.g., Uzbek, even display borrowed prefixes.

The syllable contains minimally a vowel with maximally one preceding and one subsequent consonant. Vowel hiatus and consonant clusters are avoided.

Most languages exhibit eight short vowel phonemes, *a*, *ï*, *o*, *u*, *e*, *i*, *ö*, *ü*, classified according to the features front vs. back, unrounded vs. rounded, and high vs. low. Proto-Turkic long vowel phonemes are preserved in Turkmen, Yakut, and Khalaj. Iranian and Slavic phonetic influence has sometimes affected the front vs. back distinctions. Tatar, Bashkir, Chuvash, and Uyghur exhibit systematic vowel shifts. Chuvash, Gagauz, Karaim, etc., have developed palatalized consonants, e.g., Karaim *ḿeń* 'I'. Tuvan and Tofan exhibit a glottal element signaling strong obstruents, e.g., *aʔt* 'horse' vs. *at* 'name.'

The most general sound harmony phenomenon is an intrasyllabic front vs. back assimilation. An intersyllabic front vs. back harmony causes neutralization of the front vs. back distinction under the influence of the preceding syllable. If applied consistently, it excludes back and front syllables in a word, e.g., Turkish *ev-ler-im-e* [house-PL-POSS.1.SG-DAT] 'to my houses,' *at-lar-ım-a* [horse-PL-POSS.1.SG-DAT] 'to my horses.' Some languages only display this kind of harmony, whereas others also apply a rounded vs. unrounded harmony, neutralization of the distinction rounded vs. unrounded in high suffix vowels, e.g., Turkish *el-im* [hand-POSS.1.SG] 'my hand,' *gül-üm* [rose-POSS.1.SG] 'my rose.' Languages such as Yakut and Kirghiz apply this harmony to low-vowel suffixes as well, e.g., *börö-lör* [wolf-PL] 'wolves.' There are numerous exceptions to harmony rules in loanwords. Further allomorphs are created by various consonant assimilations.

The rules of word accent vary. A high pitch accent, interacting with a dynamic stress accent, mostly falls on the last accentable syllable of native words.

The morphological structure has remained relatively stable through the centuries. The main word classes are nominals (nouns, adjectives, pronouns, numerals) and verbals. The primary stems can be used as free forms, e.g., *at* 'horse,' *at!* 'throw!.' From verbal and nominal stems, which are sharply distinguished, expanded stems are formed. Nominals take plural, possessive, case, and specific derivational suffixes. Grammatical gender is not marked. The verbal morphology comprises markers of actionality, voice, possibility, negation, aspect, mood, evidentiality, tense, person, interrogation, etc. Voice is expressed by passive, reflexive-middle, causative, and cooperative-reciprocal suffixes. The order and combinability of suffixes is basically common to all Turkic languages.

Constructions with postposed auxiliary verbs (postverbs) express actional modifications. A few constructions have developed into aspect-tense categories, e.g., Turkish *gel-iyor* [come-PRES] 'comes' < **gel-e yorï-r* [come-CONV run-AOR] ('runs coming'). Possibility markers are formed with auxiliary verbs such as *bil-* 'to know' and *al-* 'to take,' e.g., Kirghiz *ber-e al-*[give-CONV AUX.POTEN] 'to be able to give.'

Turkic languages share many syntactic characteristics. With respect to relational typology, they adhere to the nominative-accusative pattern. They have a head-final constituent order, with dependents preceding their heads. The unmarked order of clause constituents is subject + object + predicate (SOV). Adjectival, genitival, and participial attributes precede the head of the nominal phrase. Postpositions are used instead of prepositions. There is no agreement in number or case between dependents and heads. The focus position is in front of the predicate core. The unmarked constituent order is often deviated from for discourse-pragmatic reasons. Contact-induced word order changes are common, e.g., in Gagauz, which has become an SVO language.

Preposed subordinate clauses are based on verbal nouns, participles, and converbs. The use of postposed subordinative patterns with conjunctions are typical effects of Iranian and Slavic influence. Most languages possess conjunctions, even coordinative ones meaning 'and,' 'or,' and 'but' of Persian, Arabic, or Russian origin.

Turkic lacks definite articles. The indefinite article is formally identical with the numeral 'one' Genitival attributes, expressing a possessor, stand in the genitive, whereas their head, indicating a possessed entity, carries a possessive suffix, e.g., Turkish *at-ın baş-ı* [horse-GEN head-POSS.3.SG] 'the head of the horse.' The dominant type of nominal compounds follows the pattern noun + noun + possessive suffix, e.g., Turkish *el çanta-sı* [hand bag-POSS.3.SG] 'handbag.'

All Turkic varieties exhibit numerous loanwords. Arabic and Persian loans are frequent in all Islamic-Turkic languages. The Iranian influence is strong in Uyghur, Uzbek, and varieties of Iran and Afghanistan. Many languages have been subject to considerable Mongolic and Slavic influence. Loans and calques from European languages have become increasingly important. The Turkic languages spoken in China exhibit old and recent loans from Chinese.

Turkish (natively *Türkçe*), the official language of the Republic of Turkey, is spoken by a large proportion of the Turkish population. There are also Turkish speakers in the Balkans, particularly in Greece, Bulgaria, and the former Yugoslavia, although there has been extensive population inflow from those countries into Turkey, and there is a substantial minority of Turkish speakers in Cyprus. There are Turkish-influenced Turkic dialects in Iraq in the region of Kirkuk, where the speakers are called

Turkmen or Turkomans. The *Ethnologue* entry for Turkish gives a population of roughly 46 million speakers in Turkey, and 61 million in all countries.

Turkish belongs to the southwestern, or Oghuz (*Oğuz*), group of Turkic languages. This group also includes Azerbaijani, spoken in Azerbaijan and in adjacent areas of Iran; Qashqay and related dialects, spoken in the Zagros mountain area of Iran; Türkmen, spoken in Turkmenistan; and Gagauz, spoken in Bulgaria, in Romania, and principally in Moldova, although there has been substantial migration from Moldova to Turkey. Central Asian Turkic languages include the national languages of Kazakhstan, Uzbekistan, and Kyrghyzstan, and a number of others. Turkic, in turn, belongs to the Altaic family of languages, which also includes the Mongol and Manchu-Tunguz language families. Though this relationship has recently been called into question, it was proved convincingly by Poppe more than a generation ago (Poppe, 1960). Wider affinities of the Altaic family have been suggested for Korean, and even for Japanese.

Turkish scholars divide the history of the Turkish language into three periods: (1) Old Anatolian Turkish (*Eski Anadolu Türkçesi*), comprising texts dating from the earliest arrival of Turkic speakers in Anatolia, through the Seljuk period to the formation of the Ottoman Empire; (2) Ottoman (*Osmanlıca*), the language of the Ottoman Empire, heavily influenced by Arabic and Persian; and (3) Modern Turkish (*Yeni Türkçe*), dating from the overthrow of the Ottoman Empire and from the Turkish language reform movement of the 1920s and 1930s. The Turkish language reform movement was launched by Atatürk as part of his overall plan to distance Turkey from Middle Eastern, specifically Arabic and Persian, influences, in favor of European influence. This movement in the language area included most noticeably the replacement of the Arabic writing system with a Latin alphabet in 1928, and a drive to replace Arabic and Persian vocabulary, once pervasive in Ottoman texts, with vocabulary drawn or constructed from Turkish sources, or Turkish-looking inventions. The drive to cleanse the lexicon has waxed and waned over the interim and has acquired political correlates: writers on the left tend to use neologisms; those on the right use a more traditional vocabulary. There has been no corresponding attempt to rid the lexicon of European or English terminology (for more on the language reform movement, see Lewis (1999)). In 1997, a committee of the American Association of Teachers of Turkic Languages attempted to create a standardized English terminology for Turkish, which is used here.

Phonology

Phonemes

Consonants The International Phonetic Association (IPA) representations of the Turkish consonant system are shown in Table 1. Turkish uses 21 letters for consonants: b c ç d f g ğ h j k l m n p r s ş t v y z. These represent the expected sounds, except as follows:

Letter	Sound
c	[dʒ]
ç	[tʃ]
j	[ʒ]
ş	[ʃ]

In the following discussions, [tʃ] and [dʒ] will henceforth be written /č/ and /ǰ/, since they function in all phonological respects as members of the natural class of stops, not as clusters. The letters *k g l* each stand for two sounds: a plain velar or lateral [k g l] and a front velar or palatal [c ɟ ʎ]. In words of Turkish origin, the front velar variant occurs with front vowels and the plain velar occurs with back vowels. In words of Arabic origin, however, /c ɟ ʎ/ can occur with back vowels, giving rise to pairs and thus distinctive contrasts, as in *kar* 'snow' [kɑr] and *kâr* 'profit' [cɑr].

The letter *ğ*, or *yumuşak ge* 'soft g', has no consonantal sound. It normally represents an historical or underlying /g/ that has been deleted; in some Anatolian dialects, it survives as a voiced fricative [ɣ]. Most commonly, *ğ* lengthens the preceding vowel in syllable-final (coda) position, and represents nothing between vowels, as in *dağ* 'mountain' [dɑː] and *dağa* 'mountain (dat)' [dɑɑ].

Vowels Turkish vowels are traditionally represented in a 'cube' shape, consisting of all possible values of the features, front/back, high/low, and rounded/unrounded, as in Figure 1. Each vowel can occur long, from the deletion of *ğ*, and the vowels /e i a u/ can occur long in Arabic loanwords, giving a total of 16 vowel phonemes. The vowel letters are for the most part self-explanatory, except for *ı*, an undotted

Table 1 International Phonetic Association symbols for Turkish consonants

Labial	*Dental*	*Palatal*	*Front velar*	*Velar*	*Glottal*
p	t	tʃ	c	k	
b	d	dʒ	ɟ	g	
f	s	ʃ			h
v	z	ʒ			
m	n				
	l	ʎ			
	r	ʎ			

Figure 1 Turkish vowels. Front vowels are represented at the front of the cube, high vowels are at the top, and rounded vowels are to the right. Reproduced with permission from MIT Press.

Table 2 Turkish vowel harmony

Stem	*Gloss*	*Dative*	*Objective*
bal	'honey'	*bala*	*balı*
kıl	'hair'	*kıla*	*kılı*
ok	'arrow'	*oka*	*oku*
buz	'ice'	*buza*	*buzu*
ev	'house'	*eve*	*evi*
il	'province'	*ile*	*ili*
göl	'lake'	*göle*	*gölü*
gül	'rose'	*güle*	*gülü*

'i,' which is a high back unrounded vowel, IPA [ɯ]. All Turkish vowels are phonetically lax, except sometimes before *y* or *ğ*, thus *a e i ı o ö u ü* sound like [ɑ ɛ ɪ ɯ ɔ œ ʊ ʏ]. Because the difference between *ı* and *i* is distinctive, it must be maintained for capitals also, i.e., *I* and *İ*.

Stress Stress in Turkish consists of higher pitch, rather than greater loudness on the accented syllable. Stress is normally on the last syllable of the word; as affixes are added, stress moves rightward:

(1) él 'hand'
ellér 'hands'
ellerím 'my hands'

There are a number of exceptions to final stress. Some words have inherent nonfinal stress, and in these cases stress does not move with the addition of affixes. Inherently stressed words include most loans, which have their own rule for accent; in such cases, the accent may fall on a syllable other than that which is stressed in the source language, as in *sinéma* 'cinema' and *Kenédi* 'Kennedy'. Some affixes are prestressing; stress then falls on the preceding syllable and remains there as additional affixes are added. The rules for stress and much else in Turkish phonology are extensively worked out in Demircan (2001).

Phonological Rules

Turkish being an agglutinating language, suffixes are added to stems in such a manner that segmentation is relatively easy. However, a number of changes take place in both stems and suffixes when this happens.

Vowel Harmony Vowel harmony involves the two features front/back and rounded/unrounded. It is a syllable-to-syllable process by which each vowel conditions the following vowel, according to the following rules:

1. Any of the vowels can occur in the first syllable of a word.
2. A noninitial vowel assimilates to the previous vowel in frontness.
3. A noninitial high vowel assimilates to the previous vowel in rounding. A noninitial low vowel is unrounded. Thus /o ö/ do not appear in harmonic suffixes.

The process is illustrated in Table 2, which shows how the stem, dative (suffix *-yA*), and objective (suffix *-yI*) case forms of a set of nouns are used (in morphophonemic transcription, the symbol *A* represents the alternation between /a/ and /e/, and the symbol *I* represents the alternation /i ı u ü/). A few native words and very many foreign words are nonharmonic, such as *kardeş* 'brother', *otel* 'hotel', and *sigorta* 'insurance'. This has led some scholars to claim that vowel harmony no longer holds for stems (Clements and Sezer, 1982). In the case of a nonharmonic word, suffixes are controlled by the last syllable, as in *asansör* 'elevator' (plural *asansörler*) and *kredikart* 'credit card' (plural *kredikartlar*).

Other Phonological Rules Beyond vowel harmony, stems and suffixes have a highly changeable nature. Suffix-initial voiced stops devoice after a stem ending in an unvoiced consonant. Many suffixes have different postconsonantal and postvocalic forms. Stems also undergo a number of rules designed to maintain canonical syllable structure, particularly in closed syllables. Among the rules applying to syllables are final devoicing, epenthesis, degemination, and vowel shortening. There are many details concerning these rules, but as an extreme example, the verbal noun suffix best written as *-DIg* has 16 forms:

-dik/dık/duk/dük/tik/tık/tuk/tük/diğ/dığ/duğ/düğ/tiğ/tığ/tuğ/tüğ

Morphology

Turkish is an agglutinating language in which suffixes, in some cases a large number of them (the

lists of suffixes in the following sections are not exhaustive), are added fairly transparently to stems:

(2)

ev	'house'
evler	'houses'
evlerim	'my houses'
evlerimiz	'our houses'
evlerimizde	'in our houses'
evlerimizdeki	'which is in our houses'

The Noun Paradigm

Noun stems may have the following inflectional suffixes, in order:

1. Plural *-lAr* (as in *baba* 'father', *babalar* 'fathers' and *deve* 'camel', *develer* camels).
2. Possessive (possessed agreement).
3. Case (as in *oda* 'room').

(3)

Nominative:	oda
Genitive (-(n)In):	odanın
Dative (-yA):	odaya
Objective (-yI):	odayı
Locative (-DA):	odada
Ablative (-DAn):	odadan
Instrumental/comitative (-y-lA):	odayla

The Verb Paradigm

Starting with the verb root, a number of derivational suffixes can be added to build up the verb stem. These include reflexive, reciprocal, causative, passive, impossibility, negative, and abilitative forms. At this point, from the verb stem, it is possible to go in a number of directions. For a finite ('tensed') verb, the next step is a tense suffix, followed normally by a personal ending:

(4)

General present:	gelirim	'I come', 'I'll come'
Progressive:	geliyorum	'I am coming'
(Definite) past:	geldim	'I came'
Unwitnessed past:	gelmişim	'I (supposedly) came
Future:	geleceğim	'I will come'
Necessitative:	gelmeliyim	'I ought to come'
Optative:	geleyim	'let me come'
Conditional:	gelsem	'if I come'

There is also a wide range of nonfinite suffixes possible at this point for the formation of subordinate clauses. These include verbal nouns or nominalizations, participles, and adverbial clause suffixes (traditional 'converbs').

Auxiliary Suffixes

Finally, there is a group of suffixes that can be categorized under the heading of 'auxiliary'. They can be added both to verbal and nonverbal predicates, hence a separate auxiliary category. They include most prominently the personal endings, but also some morphemes that can be called 'aspects', although they are not all aspects any more than the tenses are all tenses (abbreviations: SG, singular; PROG, progressive):

(5) Yorgun -du -m.
tired -PAST –1SG
'I was tired'.

(6) Gel -iyor -du -m.
come -PROG -PAST -1SG
'I was coming'.

The aspects are past *-y-DI*, dubitative *-y-mIş*, and conditional *-y-sA*. Furthermore, there is an adverbial aspect *-y-ken*. These look very similar to some tenses, i.e., definite past *-DI*, unwitnessed past *-mIş*, and conditional *–sA*, but they differ in morphology, meaning, and prosody (all auxiliary suffixes are prestressing).

The inferential/quotative, sometimes called dubitative (DUB), *-y-mIş*, deserves special discussion. This aspect, and to some extent the corresponding tense, *-mIş*, are used when the speaker wishes to be disassociated from the truth of the utterance – for example, when the speaker has information that has only been heard or recently found out (VB, verb):

(7) Sen tembel -miş -sin.
you lazy -DUB -2SG
'They say you are lazy'.

(8) Geçen sene hasta -lan-mış-sın.
past year sick -VB-DUB–2SG
'(I heard) you got sick last year'.

The dubitative can also be used for statements for which the speaker does have personal knowledge of the fact, but is expressing something unexpected or surprising – for example, after trying a food that the speaker had expected to dislike:

(9) Bu yemek iyi -miş!
this food good -DUB
'This food is good!'

Syntax

Unmarked (normal) word order is subject-object-verb, as shown in the following example (OBJ, objective; DAT, dative):

(10) Hasan mektub -u
Hasan letter -OBJ
Ayşe-ye gönder -di.
Ayşe-DAT send -PAST
'Hasan sent the letter to Ayşe'.

However, this is complicated by the fact that Turkish has pragmatically conditioned word order, by which the information status of noun phrases, rather than

their grammatical function, determines their placement in the sentence. Many of the basic principles were worked out by Erguvanlı (1984). The topic is sentence initial; thus, any of the terms of Example (10) could be initial, depending on whether Hasan, the letter, or Ayşe is the topic. New information comes in the preverbal position, thus any of the terms of Example (10), if indefinite, would move preverbally:

(11) Mektub-u Ayşe-ye bir
letter-OBJ Ayşe-DAT a
arkadaş gönder-di.
friend send-PAST
'A friend sent the letter to Ayse'.

In fact, preverbal position is focus position; thus, *wh*-words are found here, as well as words questioned contrastively, the focused words in the answers to *wh*-questions, or any focused argument. Though the canonical sentence pattern for English might be written as subject-verb-object-X, where X is everything else, the pattern for Turkish would be topic-X-focus verb, and is thus determined by pragmatic rather than by grammatical conditions. Furthermore, sentences are not necessarily verb final. Backgrounded or unstressed information can move to the right of the verb, producing what is traditionally called a *devrik cümle* (*tümce*), or 'inverted sentence' (NEG, negative; PL, plural):

(12) Ver-me çocuğ-a kibrit-ler-i.
give-NEG child-DAT match-PL-OBJ
'Don't give the child the matches'.

The focus in Example (12) is 'don't give,' and the child and the matches will have been previously mentioned or are clear in the context, i.e., are 'given' in the sense of functional syntax.

Turkish is a left-branching and head-final language in which nouns follow adjectives (Example (13)), possessives (Example (14)), and relative clauses (Example (15)); postpositions follow noun phrases (Example (16)), and verbs follow direct objects, even subordinate clauses (Example (17)) (GEN, genitive; POSS, possessive; LOC, locative; PART, participle; ABL, ablative; VN, verbal noun; FUT, future):

(13) çok küçük bir çocuk.
very small a child
'A very small child'.

(14) Enver-in şapka-sı.
Enver-GEN hat-POSS
'Enver's hat'.

(15) Köşe-de otur-an kız.
corner-LOC sit-PART girl
'The girl who is sitting in the corner'.

(16) Bu haber-den dolayı.
this news-ABL because
'Because of this news'.

(17) Hasan-ın yarın
Hasan-GEN tomorrow
gel-eceğ-in-i duy-du–m.
come-VN.FUT–3SG-OBJ hear-PAST–1SG
'I heard that Hasan will come tomorrow'.

Notice from Example (17) that Turkish is a pro-drop language ('pronoun dropping'; i.e., subject pronouns normally are not used, as in Latin or Spanish). Overt pronouns appear in cases of focus or contrast, including topic change. Because relative clauses precede head nouns, and direct objects (including noun complement clauses) precede the main verb, Turkish sentences sometimes give the impression of having the reverse word order from English. English speakers reading Turkish sometimes find it easier to start at the end of a sentence and read toward the front, and Turkish speakers report that they do the same in reading English.

Turkish Lexicography

O Bilgin, Bosphorus University, Istanbul, Turkey

© 2006 Elsevier Ltd. All rights reserved.

The earliest known lexicon of Turkic languages is the *Diwan lûgat at-Turk* (Compendium of Turkic dialects), which was compiled by Mahmud al-Kashgari in the 11th century. According to its author, the *Diwan* was prepared in Baghdad between 1072 and 1074 and presented to an Abbasid caliph. The *Diwan* is an encyclopedic Turkish-Arabic lexicon aimed at teaching Turkish to Arabs and contains approximately 7500 headwords, accompanied by rich information on Turkish ethnography, history, and literature. The entries are ordered not alphabetically but according to three-letter Arabic roots and provide usage examples taken from elegies and proverbs.

An important lexicon of 18th-century Ottoman Turkish is Francisci a Mesgnien Meninski's four-volume *Lexicon Turcico-Arabico-Persicum* (Turkish-Arabic-Persian lexicon), which was published in Vienna in 1780. Each entry begins with the orthographic form in the Arabic alphabet, followed by a transcription in the Latin alphabet and a field indicating whether the word is of Turkish, Arabic, or Persian origin. The Latin transcription provides valuable information on 18th-century pronunciation, since it distinguishes between the Turkish round vowels [o], [œ], [u], and [y]. In lexicons using the Arabic script, these vowels are all represented by the Arabic letter و which makes it impossible to arrive at the correct pronunciation from the orthographic form.

Statesman and author Ahmed Vefik Pasha's *Lehçe-i Osmanî* (The Ottoman dialect) is a two-volume dictionary of 19th-century Ottoman Turkish published in 1888. Vefik Pasha was an early proponent of Turkish nationalism and the 'purification' of the Turkish language, and the *Lehçe-i Osmanî* reflects this political orientation. According to Vefik Pasha, Ottoman Turkish was not a separate language but only a dialect that had been invaded by Arabic and Persian elements – and later by the languages of Europe, particularly French – which should be removed from the language. In keeping with this idea, which would become a major issue in Turkish lexicography in the 20th century, Vefik Pasha dedicated the first volume of his dictionary exclusively to words of Turkish origin, while the second volume contained frequently used foreign words.

Another major general dictionary of Ottoman Turkish, *Kamus-ı Türkî*, was published by author and lexicographer Shemseddin Sami Bey in Istanbul in 1901. The *Kamus* is an alphabetically ordered general dictionary containing a substantial number of multi word entries, parts-of-speech information, subject domain information, and etymologies for Arabic, Persian, and French loanwords. Unlike Ahmed Vefik Pasha's *Lehçe-i Osmanî*, the *Kamus-ı Türkî* is a descriptive work that presents words of Turkish, Arabic, Persian, and French origin side by side.

An extremely influential English-Turkish dictionary is *A lexicon, English and Turkish* . . published by Sir James W. Redhouse in 1861 (Figure 1). The bilingual general dictionary contains 93 000 English headwords and their pronunciation, followed by their Turkish equivalents and definitions in Arabic script. Redhouse also published a Turkish-English dictionary entitled *Kitab-ı Maani-i Lehçe* (A Turkish and English lexicon) in 1890. These two original works

have been transcribed, extended, and modified several times and are still in print today.

With the shift from the Arabic alphabet to the Latin alphabet in 1928, dictionaries that had been published in the Arabic alphabet over the centuries gradually became inaccessible to the public at large. The alphabet change coincided with the new Republic's nationalistic campaign to 'purify' the language. The Turkish Language Association (TDK) was established in 1932, and the monolingual Turkish dictionary compiled by this institution is still the most influential general dictionary of the Turkish that is spoken and written in modern Turkey.

The first edition of TDK's *Türkçe Sözlük* (Turkish dictionary), published in 1945, contains a considerable number of newly coined words and revived old Turkish words aimed at expelling Arabic, Persian, Latin, and Greek elements from the lexicon. The dictionary was considerably expanded and modified in successive editions. Newly coined or revived words that had obviously failed to gain public support were removed from the dictionary in later editions. The eighth (and most recent) edition, printed in 1988, is also available online.

The history of TDK's *Türkçe Sözlük* is full of political struggles that manifested themselves in the form of questions as to whether or not words of foreign origin should be included, how far the dictionary's compilers should go with coining new terms, what kind of standard spelling should be adopted, and whether or not usage examples from authors not favored by the state should be included. The debate around the 'purification' campaign was so intense that literary historian and linguist Faruk K. Timurtaş felt obliged to publish a small handbook in 1979, entitled *Uydurma Olan ve Olmayan Yeni Kelimeler Sözlüğü* (Dictionary of new words, fabricated and non-fabricated). Whatever the merits of this heated debate may be, hundreds of words and various roots and suffixes coined or revived by the TDK have now become a standard part of Turkish.

An important lexical resource is the 12-volume *Derleme Sözlüğü* (Compilation of Turkish words), compiled by the TDK between 1932 and 1982. This is an extensive survey of words used within the territory of the Republic of Turkey and is based on a collection of 600 000 index cards sent in by almost one thousand volunteers from all over the country, including the most remote villages. The *Derleme Sözlüğü* is a major dialectological repository of 20th-century Anatolian Turkish and provides valuable information on the history, phonology, and morphology of the language.

Another reference source published by the TDK is the *Tarama Sözlüğü* (Survey of Turkish texts), prepared between 1935 and 1977 by experts in Ottoman Turkish. The *Tarama Sözlüğü* is a survey of words found in more than 200 manuscripts and printed works written in Turkish between the 13th and 19th centuries. The work was later expanded and published in eight volumes (1963–1977). An abbreviated, single-volume version was published in 1983.

The TDK also published a two-volume English-Turkish dictionary in 1999. The dictionary, compiled by Hamit Atalay, contains 180 000 English entries with parts-of-speech information, Turkish translations, Turkish definitions, fine sense distinctions, usage examples, synonyms, and antonyms.

The rapid rate of language change in 20th-century Turkey gained further momentum beginning in the 1950s, which gave rise to the need for Ottoman Turkish/modern Turkish dictionaries. A reputable and large-scale example of this kind is Ferit Devellioğlu's *Osmanlıca-Türkçe Ansiklopedik Lûgat* (Ottoman-Turkish encyclopedic dictionary) (1962), which contains 60,000 entries together with Arabic and Latin transcriptions, parts-of-speech information, and etymologies. The three-volume *Osmanlı Tarih Deyimleri ve Terimleri Sözlüğü* (Dictionary of Ottoman historical terms), published by the Turkish Ministry of National Education in 1983, is an encyclopedic dictionary compiled by Mehmet Zeki Pakalın that is a rich repository of the linguistic and cultural heritage of the Ottoman Empire.

Pars Tuğlacı (b. 1933), a Turkish citizen of Armenian origin, is a major lexicographer of Turkish who has compiled a wide variety of lexicons. His 10-volume *Okyanus* encyclopedic dictionary (1971–1974) is the largest lexicon of Turkish prepared by a single individual. It contains usage examples, parts-of-speech information, word origins, color illustrations, and English and French translations for approximately 200 000 lexical items, including a substantial number of multiword expressions. Tuğlacı has also published an English-Turkish medical dictionary, a dictionary of economic and legal terms, a French-Turkish dictionary, a dictionary of English idioms, and a collection of synonyms and antonyms in Turkish.

In the 20th century, special subject dictionaries were mainly compiled by individuals who were not necessarily lexicographers. Common problems with these resources include the almost total absence of teamwork, lack of a scientific system for word list preparation, inconsistent spelling practices and definitions, mistakes carried over from earlier sources, deviations from descriptive principles reflecting the political orientation of the author, low print runs, and inadequate promotion. Notable exceptions are the *Türk Hukuk Lûgati* (Turkish law dictionary), prepared by the *Türk Hukuk Cemiyeti* (Turkish Law

Association) (1943); the two-volume English-Turkish-English *Hukuk Sözlüğü* (Law dictionary) by Mustafa Ovacık (1964); *Açıklamalı Tıp Terimleri Sözlüğü* (English-Turkish explanatory dictionary of medical terms) by Utkan Kocatürk (2000); *İngilizce-Türkçe Reklam Terimleri ve Kavramları Sözlüğü* (English-Turkish dictionary of advertising terms) by Tanses Gülsoy (1999); and *İngilizce-Türkçe Ansiklopedik Bilişim Sözlüğü* (English-Turkish encyclopedic dictionary of IT terms) (2002).

With the advent of personal computers and the Internet, a limited number of online glossaries emerged starting in the late 1990s. Current resources are mere transfers of existing printed resources, or worse, compilations from various unknown sources. Zargan is the publisher of a major online Turkish-English-Turkish terminology bank containing 435 000 entries, with special emphasis on business terms.

Ongoing lexicography projects using computer technology focus on online collaboration possibilities, error-reporting systems, automatic detection and sorting of missing entries based on user queries and corpus data, cross-linking of online resources, the integration of online lexical resources into word processors, and the development of intelligent search algorithms using spelling correction systems and morphological analyzers, the latter being an absolute necessity for an agglutinating language like Turkish.

Recent academic projects include Sabancı University's Turkish WordNet, which contains 13 000 concepts, and Berkeley University's Turkish Electronic Living Lexicon, which is a database of 30 000 Turkish words, representing both print dictionaries and actual speaker knowledge. The latter includes orthographic representations, phonemic transcriptions, morphological roots, and etymologies. Another center of academic activity on the Turkish language is the Middle East Technical University in Ankara, whose Informatics Institute has published a treebank and a balanced corpus for lexical studies in Turkish.

Turkmen

L Johanson, University of Mainz, Mainz, Germany

© 2006 Elsevier Ltd. All rights reserved.

Location and Speakers

Turkmen (*türkmen dili, türkmenče*) belongs to the southwestern or Oghuz branch of the Turkic language family, which also includes Turkish. It is mainly spoken in Turkmenistan (*Türkmenistan döwleti*), which is located in the Transcaspian region and whose capital is Ashgabat. Turkmenistan borders on Iran and Afghanistan in the south, Uzbekistan in the east, and Kazakhstan in the north. The area of distribution of Turkmen extends from the southeastern shore of the Caspian Sea to the Kazakh-speaking area in the north, the Karakalpak-speaking area in the northeast, the Uzbek-speaking area in the east, beyond the Amudarya River, and the Persian (Farsi, Western) and Khorasan Oghuz (Khorasani Turkish) areas in the south, beyond the borders to Afghanistan and Iran. Though Turkmens make up 85% of the 4.8 million inhabitants, only 72% speak Turkmen. The other main languages are Russian (12%) and Uzbek (9%). Turkmen-speaking groups also live in the Russian Federation, Kazakhstan, Tajikistan, China, etc. The total number of speakers amounts to nearly 5 million.

The designation 'Turkmen' is not unequivocal. Older Oghuz varieties spoken in Khorezm, Khorasan, Azerbaijan, Anatolia, and other regions in the Near East were referred to as 'Turkmen.' Several nomadic groups in Anatolia, Iraq, etc. are still called 'Turkmen' without being Turkmen in a linguistic sense.

Since the mid-1990s, language policy aims at consolidating Turkmen as the state language and to remove the Russian dominance. Turkmen is gaining more social functions. The 1992 constitution defines it as the "official language of inter-ethnic communication." Geographic names and administrative terms have been changed from Russian to Turkmen. In practice, however, Russian has maintained its importance in most spheres of public communication.

Origin and History

The Turkmens go back to the Turkic-speaking Oghuz confederation of tribes, whose Inner Asian steppe empire collapsed in 744. Certain Oghuz groups migrated into the region between the Syrdarya and Ural rivers. By the late 10th century, the Seljuk dynasty was founded, and an autonomous state was established on the lower Syrdarya. The Seljuks left this region in the middle of the 11th century and migrated westwards. Their modern descendants are the Turks of Khorasan, Azerbaijan, and Turkey. The speakers of Turkmen are mainly descendants of non-Seljuk groups that did not take part in these migrations.

During the Mongol conquests in the 13th century, the remaining Oghuz tribes were pushed into the Karakum desert and the region east of the Caspian Sea. From the 16th century on, Turkmen groups migrated to Khorezm, to the southern part of today's Turkmenistan, and to Khorasan, absorbing local Turkic and Iranian elements. The major migrations of the Salïr, Ersarï, Sarïq and Teke tribes took place in the 17th century. In the 18th century, the Turkmens conquered the whole core area that they inhabit today.

Most tribes were subsequently divided and controlled by the Uzbek khanates of Khiwa and Bukhara, while the Persian shahs tried to subdue the southern tribes. The dependence of Khiwa and Persia came to an end after the mid-19th century. Some decades later, Russia annexed the Turkmen territory, which caused many Turkmen groups to emigrate to Afghanistan and Iran. The Turkmen area was first administered as the Trans-Caspian district in the Governorate of Turkistan. In 1924, Turkmenistan was proclaimed a Socialist Soviet Republic.

In connection with the dissolution of the Soviet Union, Turkmenistan declared its sovereignty in 1990, achieved its independence in 1991 (after a popular referendum), and adopted its new constitution in 1992.

Related Languages and Language Contacts

The closest relative of Turkmen is Khorasan Turkic (Khorasani), spoken in northeastern Iran and Khorazm, a distinct language with which it constitutes the eastern subbranch of Oghuz. Azerbaijanian (Azerbaijani) and Turkish represent the western subbranch. The specific features of Turkmen are partly archaic and partly innovative, due to language contact. Within the Turkic family, Khorasan Turkic, Uzbek, and Karakalpak are the most important contact languages. Turkmen has had intensive contacts with Persian and, during the last century, with Russian.

The Written Language

Old Turkmen is not clearly documented in written sources. The oldest records of 'Turkmen' relate to Oghuz varieties in general. Oghuz texts of the following centuries do not exhibit any specific Turkmen features. A written Turkmen literature began in the 18th century, but the language used is a variety of the

classical Chaghatay (Chagatai) language. A Turkmen standard language was created in the Soviet era and formed mainly from 1928 on. It was based on the Teke dialect as spoken in the Ashgabat region.

Arabic script was used in the first period. Two script reforms, in 1922 and 1925, aimed at reflecting spoken features more adequately. A Roman-based alphabet that reflected most of these features rather accurately was in use from 1928 to 1940. A variant of the Cyrillic alphabet was adopted in 1939–1940. Since the early 1990s, there has been a transition to a Roman-based script again. In 1993, the final version of a Roman-based alphabet was adopted to replace the Cyrillic one. It has several unique letters that distinguish it from Turkey's alphabet and the newly adopted alphabets of other Turkic republics.

Distinctive Features

Turkmen exhibits most linguistic features typical of the Turkic family (*see* **Turkic Languages**). It is an agglutinative language with suffixing morphology, sound harmony, and a head-final constituent order. In the following, only a few distinctive features will be dealt with. In the notation of suffixes, capital letters indicate phonetic variation, e.g., *A* = *a/e*, *I* = *ï/i*. Segments in round brackets only occur after consonant final stems. Hyphens are used here to indicate morpheme boundaries.

Phonology

Turkmen has, like Yakut and Khalaj, preserved Proto-Turkic long vowels in a consistent way, e.g., *a:t* 'name' < *a:t* (but at 'horse' < *at*), *dö:rt* 'four' vs. Turkish *dört* < *tö:rt*. The orthography does not normally mark vowel length, but *ü*: in words of Turkic origin is expressed by *üy*, e.g., *süyt* for [θü:t] 'milk'. Proto-Turkic *e:* is mostly represented by Turkmen *i*, which mostly corresponds to Azerbaijanian *e*, e.g., *gi:č* 'late' (Azerbaijanian *geč*, Turkish *geç*).

A striking feature of Turkmen pronunciation is the presence of the interdental fricatives *θ* and *δ*, which correspond to *s* and *z* in other Turkic languages, e.g., *θiδ* 'you' (Turkish *siz*).

As in Azerbaijanian, the word-initial back velar *ġ*- corresponds to *q*- in other Turkic languages, e.g., *ġï:δ* 'girl' (Azerbaijanian *ġïz*, Turkish *kız*). Initial *b*- is preserved in *ber*- 'to give', *ba:r* 'existing', *bar*- 'to go' and *bol*- 'to become' (Turkish *ver*-, *var*, *var*-, *ol*-). The bilabial fricative *β* is used instead of labiodental *v*, e.g., *a:β* 'hunt' (Turkish *av*). It appears as the glide *w* between two vowels or between a liquid and a vowel. The bilabial fricative *f* is frequently replaced by the stop *p* in loans, e.g., *pikir* 'thought' (Turkish *fikir*).

Suffix vowels mostly assimilate to the quality of the preceding vowel. Turkmen displays both front vs. back harmony and rounded vs. unrounded harmony. The latter also includes suffixes with low vowels, e.g., *toy-do* [feast-LOC] 'at the feast' vs. *öy-dö* [house-LOC] 'in the house'. Long *a:* and *e:* are not rounded; there are also other exceptions. Though the orthography represents the vowels of rather closely, rounding harmony is not consistently represented. Rounding is only expressed in high vowels and not beyond the second syllable. The tendency towards rounded low suffix vowels is also observed in languages such as Kirghiz, Altay Turkic (Altai), and Yakut.

Numerous consonant assimilations are observed, e.g., *men-ne* [I-LOC] 'in me', *ġïδ-δan* [girl-ABL] 'from the girl', *yol-loš* [way-DER] 'comrade' (Turkish *ben-de* [I-LOC], *kiz-dan* [girl-ABL], *yol-daş* [way-DER]). They are mostly not reflected in the orthography.

In copies of loanwords, nonpermissible consonant clusters are dissolved by means of prothetic or epenthetic vowels, e.g., *uθθul* 'chair' < Russian *stul*, *pikir* 'thought' < Arabic *fikr*. In recent loanwords from Russian, these vowels are not reflected orthographically.

Grammar

The comparative degree of adjectives is formed with *-rA:K*, e.g., *kičire:k* [small-COMP] 'smaller, rather small' (*kiči* 'small'). The demonstrative pronouns *bu:*, *šu:*, *ol* and *šo[l]* form a fourfold deictic system, expressing various degrees of distance (Turkish *bu*, *o* and *şu*).

The old present tense, mostly called 'indefinite future,' is formed with *-Ar*, e.g., *bil-er* [know-AOR] 'will know' (Turkish *bil-ir* [know-AOR]), *oqa:-r* [read-AOR] 'will read' (Turkish *oku-r* [read-AOR]). The negative marker is *-mAδ* in the third person, and *-mAr* in the other persons, e.g., *gel-mer-in* [come-NEG.AOR-1.SG] 'I will not come' (Turkish *gel-me-m* [come-NEG.AOR-1.SG], Azerbaijanian *gel-mer-em* [come-NEG.AOR-1.SG]). A more focused present tense is formed with *-yA:r*, often contracted to *-yA*, e.g., *bil-ye:r* [know-PRES.3.SG] 'knows', *oqa-ya:r* [read-PRES.3.SG] 'reads, is reading'. A few verbs exhibit contracted forms without this marker: *du:r* [stand-PRES.3.SG] 'is standing', *otï:r* [sit-PRES.3.SG] 'is sitting', *yatï:r* [lie-PRES.3.SG] 'is lying'. These forms can be used with a converb marker to express a continuous present, e.g., *oqa:-p otï:r* [read-CONV AUX-PRES.3.SG] 'is reading'.

The second-person imperatives include an unmarked singular, e.g., *gel* [come.IMP.2.SG] 'come!', a form

expressing insistence, e.g., *gel-gin* [come-IMP.2.SG], a plural form, e.g., *gel-iŋ* [come.IMP.2.PL], and intensifying forms, e.g., *gel-θen-e* [come-IMP.2.SG] (singular) and *gel-θe-ŋiδ-lä:ŋ* [come-IMP.2.PL] (plural). The first-person plural has a special form that only refers to the speaker and the addressee, e.g., *gel-eli-ŋ* [come-IMP.1.PL] 'let us come', *gel-eli* [come-IMP.1.INCL] 'let us come (you and me)'.

The future marker *-ǰAK* and the intentional marker *-mAK-čI* lack personal markers, e.g., *men gel-ǰek* [I come-FUT] 'I will come' (Turkish *gel-eceğ-im* [come-FUT.1.SG]), *men yaδ-maq-či* [I write-INTENT] 'I intend to write'.

Turkmen has a postterminal ('past') participle marker *-An* and an intraterminal ('present') participle marker *-yA:n*, e.g., *bil-en* [know-POSTTERMINAL.PART] 'having known', *bil-ye:n* [know-INTRATERMINAL.PART] 'knowing'. A categorical negation is formed with the participle in *-An* + possessive suffix + *yo:q* 'non-existing', e.g., *al-amo:q* (<*al-an-ïm yo:q*) [take-POSTTERMINAL.PART-POSS.1.SG not-existing] 'I did/do not take at all'. There is a postterminal converb marker *-(I)p*, e.g., *oyno-p* [play-POSTTERMINAL.CONV] 'having played'. The corresponding marker of Turkish and Azerbaijanian displays the uncontracted form *-(y)Ip/-(y)Ib*, e.g., Turkish *oyna-yip* [play-POSTTERMINAL.CONV].

Among the evidential markers, the inflectional suffix *-(I)p-dIr*, negated *-mAn-dIr*, forms an evidential (indirective) past, e.g., *gel-ip-dir* [come-POSTTERMINAL.CONV-EV.3.SG] 'has evidently come'. The copula particle *eken* combines with various participles, e.g., *gel-en eken* [come-POSTTERMINAL. PART EV.PARTICLE] 'has obviously arrived'. The copula particle *-mIš* suggests second-hand information, e.g., *gel-ip-miš-in* [come-POSTTERMINAL. CONV-EV.3SG] 'has reportedly come'. A presumptive intraterminal (present, imperfect) is formed with *-yA:n-dIr*, a presumptive postterminal (perfect) with *-A:n-dIr*, e.g., *bar-ya:n-nïr* [go-INTRATERMINAL. PART-PRESUMP.3.SG] 'is probably going', *bar-an -nïr* [go-POSTTERMINAL.PART-PRESUMP.3.SG] 'has probably gone'.

A number of postverb constructions with converbs plus auxiliary verbs, *ġoy-* 'to put', *git-* 'to go away', *čïq-* 'to go out', *dur-* 'stand', *otur-* 'sit', *yör-* 'move', etc., express modifications of the manner in which the action denoted by the lexical verb is carried out.

Lexicon

The Turkmen vocabulary is basically of southwestern Turkic origin, though it also contains words typical of the Northwestern and Southeastern branches of Turkic. There are synonyms representing Oghuz and non-Oghuz types, e.g., *ġapï* and *išik* 'door', *dodaq* and *erin* 'lip'. The vocabulary contains numerous words of Arabic and Persian origin, borrowed from Persian and representing the traditional sphere of Islamic civilization, e.g., *xat* 'letter', *ïnθa:n* 'human being', *ša:t* 'glad', *gül* 'flower', *ireŋk* 'color'. The Turkmen conjunctions are mainly of Arabo-Persian origin, e.g., *we* 'and', *emma:* 'but'. Words of Russian origin, borrowed from the 19th century on, represent phenomena of modern life, e.g., *poθyolok* 'settlement', *ġaδyet* 'newspaper', *fe:rma* 'farm'. The vocabulary contains many recent internationalisms borrowed via Russian.

Dialects

Turkmen dialects and subdialects are referred to by the names of tribes and clans. One main dialect group comprises the Teke, Yomud, Sarïq, Salïr, Gökleng and Ersari dialects, which are rather close to Standard Turkmen. The Teke dialect, occupying the central area, has two subdialects, Marï and Akhal, the latter spoken in the Ashgabat region. The Yomud dialect is spoken on the southeast shore of the Caspian Sea and in the northern part of Turkmenistan. Ersarï dialects are spoken in the eastern part of the country. The second main dialect group is found in the regions on and beyond the borders to Iran and Uzbekistan. These dialects are more distant from Standard Turkmen, lacking, for example, the interdental pronunciation of the sibilants *s* and *z*.

An isolated variety of Turkmen is Türkpen (Russian Trukhmen), spoken by small groups (ca. 12 000) on the lower Kuma River in the Stavropol region of Northern Caucasus. Türkpen is strongly influenced by Noghay (Nogai). Its speakers are descended from Turkmen tribes that migrated here in the 18th century from the Mangyshlak region east of the Caspian Sea. Salar, spoken in western China, seems to go back to an early Turkmen variety.

Turkmenistan: Language Situation

L Johanson, Mainz University, Mainz, Germany

© 2006 Elsevier Ltd. All rights reserved.

Languages

The Republic of Turkmenistan, located in the Transcaspian region between the Caspian Sea and the Amudarya River, borders on Iran and Afghanistan in the south, Uzbekistan in the east, and Kazakhstan in the north. Four-fifths of the country consist of deserts, with the Kara-Kum desert dominating the central area. The majority of the population live in a long, narrow zone on the northern slopes of the Köpetdagh and along the Amudarya River.

Turkmenistan was annexed by Russia between 1865 and 1885, was proclaimed a Socialist Soviet Republic in 1924, and achieved its independence from the Soviet Union in 1991.

The population of Turkmenistan numbers more than 4.8 million, of which about 85% are Turkmen. No other titular nation in the Turkic republics of Central Asia reaches this high share of the total population. The rest consists of Uzbeks (5%), Russians (4%), Kazakhs, Tatars, Ukrainians, Azerbaijanians, Armenians, etc. The capital Ashgabat and some other cities have a high proportion of non-Turkmen inhabitants. The majority of the Uzbek-speaking groups live along the Amudarya River. The Kazakh-speaking area is located in the northern part of the republic. Khorasan Turkic is spoken in the southern region bordering northern Iran. Turkmen-speaking groups also live in Iran, Afghanistan, Kazakhstan, Uzbekistan, the Russian Federation, Kazakhstan, Tajikistan, China, etc. The annexation of the Turkmen territory by Russia at the end of the 19th century as well as the events of the Civil War and later socioeconomic reforms caused sizeable Turkmen groups to emigrate to Afghanistan and Iran.

The official national language of Turkmenistan is Turkmen, spoken by about 72% of the population. Russian is still spoken by 12%.

Language Policy

When Soviet Central Asia was divided into union republics in 1924, the Transcaspian District and the Turkmen Oblast of the Turkestan Autonomous Soviet Socialist Republic were transformed into the Turkmen Soviet Socialist Republic. In the following period, significant numbers of Russians and other non-Turkmens migrated to the urban areas of the republic. Standard Turkmen, based on the dialect spoken in the region around Ashgabat, was formed during the Soviet period. Education and literacy, mainly in Russian, but also in Turkmen, were strongly promoted.

In the post-Soviet period, efforts to preserve, protect, and promote Turkmen have been successful. The social functions of the language have been broadened, and its status as the state language has been consolidated. Russian was replaced as official language in the 1992 constitution, which defined Turkmen as the official language of interethnic communication. In 1993, English was given the status of a second official language. Though the language policy has been aiming at limiting the influence of Russian, this language has maintained much of its importance in official and public communication.

Turkmen has been written with Arabic script, a Roman-based alphabet, and a Cyrillic-based alphabet. In 1993, the final version of a Roman-based alphabet was adopted to replace the Cyrillic one, but the transition to this script system has been slow. Turkmenistan still applies a dual system with Cyrillic- and Roman-based scripts appearing side by side.

Turks and Caicos Islands: Language Situation

Editorial Team

© 2006 Elsevier Ltd. All rights reserved.

The Turks and Caicos Islands are two island groups in the North Atlantic Ocean, a southeastern continuation of the Bahamas. The archipelago includes more than 30 small islands, of which only eight are inhabited.

The first known inhabitants here were Taíno Indians, who were killed and forced into slavery by European settlers in the 16th century. Ownership of the territory was disputed between the French, Spanish, and British, which ended with the eventual victory of the British, although the French also ruled for some period in later history. The islands remained without a permanent population until 1678, when people arrived from Bermuda and settled there, trading in salt. Later settlers established cotton plantations, using the labor of slaves. The archipelago became part of the Bahamas in 1799 and then became self-governing in 1848. In 1872 it was annexed to Jamaica, where it remained until 1962, when it was linked to the Bahamas. In 1973 it became an overseas territory of the United Kingdom.

The population (19 956, July 2004 estimate) is mostly of African origin (90%), descended from the slaves who were brought in the 18th century. In addition, there is a mixed European and American minority (10%). Recent years have seen the rise of the number of immigrants from Haiti and the Dominican Republic.

The official language is English. At least half of the population speaks Turks and Caicos Creole English, a creole closely related to Bahamas Creole English.

Turner, Lorenzo Dow (1895–1972)

P D Fallon, Howard University, Washington, DC, USA

© 2006 Elsevier Ltd. All rights reserved.

Lorenzo Dow Turner (1890–1972) was the first African–American member of the Linguistic Society of America (LSA), and is best known for his *Africanisms in the Gullah dialect* (1949), the first groundbreaking monograph on the Gullah language (Sea Island Creole English or Geechee).

Lorenzo Dow Turner was born August 21, 1890, in Elizabeth City, North Carolina. (Later in life, Turner listed a birth date in 1893 or 1895, because grants were age restricted). Turner earned his bachelor's degree from Howard University in 1914 and completed his master's degree from Harvard University in 1917 (which he financed by working on steamboats in the summer). He became a professor in the Department of English at Howard from 1917 and its Head from 1920–1928. While on Howard's faculty, he earned a doctorate in English from the University of Chicago in 1926 (Turner, 1929). Turner also coedited an anthology of African–American literature (Cromwell, Turner, and Dykes, 1931).

Turner left Howard in 1928 to found the *Washington Sun* newspaper, but when it folded, he taught at Fisk University, where he stayed from 1929 to 1946. Turner often taught at other historically black institutions during the summers, where he was exposed to different language varieties, especially Gullah, which piqued his linguistic interest.

Turner attended the 1930 Linguistic Institute and was recruited by Hans Kurath to collect data for the *Linguistic atlas of the United States and Canada*, conducting questionnaires on Gullah and Louisiana Creole (Louisiana Creole French). Turner gained

Landau J M & Kellner-Heinkele B (2001). *Politics of language in the ex-Soviet Muslim states: Azerbaijan, Uzbekistan, Kazakhstan, Kyrgyzstan, Turkmenistan, Tajikistan*. Ann Arbor: University of Michigan Press.

Lorenzo Dow Turner (1890–1972) was the first African–American member of the Linguistic Society of America (LSA), and is best known for his *Africanisms in the Gullah dialect* (1949), the first groundbreaking monograph on the Gullah language (Sea Island Creole English or Geechee).

Lorenzo Dow Turner was born August 21, 1890, in Elizabeth City, North Carolina. (Later in life, Turner listed a birth date in 1893 or 1895, because grants were age restricted). Turner earned his bachelor's degree from Howard University in 1914 and completed his master's degree from Harvard University in 1917 (which he financed by working on steamboats in the summer). He became a professor in the Department of English at Howard from 1917 and its Head from 1920–1928. While on Howard's faculty, he earned a doctorate in English from the University of Chicago in 1926 (Turner, 1929). Turner also coedited an anthology of African–American literature (Cromwell, Turner, and Dykes, 1931).

Turner left Howard in 1928 to found the *Washington Sun* newspaper, but when it folded, he taught at Fisk University, where he stayed from 1929 to 1946. Turner often taught at other historically black institutions during the summers, where he was exposed to different language varieties, especially Gullah, which piqued his linguistic interest.

Turner attended the 1930 Linguistic Institute and was recruited by Hans Kurath to collect data for the *Linguistic atlas of the United States and Canada*, conducting questionnaires on Gullah and Louisiana Creole (Louisiana Creole French). Turner gained

additional training from the Linguistic Institutes of 1931 and 1934. Realizing the importance of the African substrate in these languages, he spent 1936 to 1937 at the University of London, studying phonetics with Daniel Jones and Lilias Armstrong, and at the School of Oriental and African Studies, studying West African languages with Ida Ward. Not long after a research fellowship at Yale, where he studied under Edward Sapir, Turner began publishing his previous studies on Africanisms in Gullah. In part because he was African–American, Turner was able to win the trust of his linguistic consultants and was able to describe a more vernacular form of Gullah than his white colleagues could.

Turner developed an interest in African cultural survivals in Brazil, studying there from 1940 to 1941. In 1946, Turner moved to Roosevelt College in Chicago. He won a Fulbright to Africa in 1951 to 1952, where he lectured in Nigeria, and where he drove 20 000 miles, conducting research on linguistics and folklore along the way. He developed language materials in Sierra Leone Krio for the Peace Corps, along with unpublished dictionaries on Brazilian and African languages, and set up several Peace Corps programs in Africa. Turner died on February 10, 1972, leaving a tremendous wealth of unpublished material from West Africa and Brazil.

Turner's greatest contribution was to rebut the assumption that there were no African retentions in the New World, using thousands of examples from all aspects of language. Turner's (1949) book paved the way for later studies in both creoles and in African American Vernacular English.

Sir Ralph Lilley Turner (IES KB MC FBA) was serving as an officer in the Gurkha Rifles during the Palestine Campaign of 1917–1918 when he conceived the plan that was to lead to *A comparative and etymological dictionary of the Nepali language* (Turner, 1931) and to *A comparative dictionary of the Indo-Aryan languages* (Turner, 1966, 1969, 1971, 1985).

Turner was born on October 5, 1888. He was introduced to Sanskrit while still at school, studied Classics and Sanskrit with comparative philology at Cambridge, and in 1913 was appointed to teach Sanskrit in Queen's College, Benares. He was, in 1920, deputed to Benares Hindu University as a professor of Indian linguistics and, in 1922, elected to the chair of Sanskrit in London University at its new School of Oriental Studies. Thus he not only influenced and worked with the rising generation of Indian historical linguists, such as S. K. Chatterji, S. M. Katre,

additional training from the Linguistic Institutes of 1931 and 1934. Realizing the importance of the African substrate in these languages, he spent 1936 to 1937 at the University of London, studying phonetics with Daniel Jones and Lilias Armstrong, and at the School of Oriental and African Studies, studying West African languages with Ida Ward. Not long after a research fellowship at Yale, where he studied under Edward Sapir, Turner began publishing his previous studies on Africanisms in Gullah. In part because he was African–American, Turner was able to win the trust of his linguistic consultants and was able to describe a more vernacular form of Gullah than his white colleagues could.

Turner developed an interest in African cultural survivals in Brazil, studying there from 1940 to 1941. In 1946, Turner moved to Roosevelt College in Chicago. He won a Fulbright to Africa in 1951 to 1952, where he lectured in Nigeria, and where he drove 20 000 miles, conducting research on linguistics and folklore along the way. He developed language materials in Sierra Leone Krio for the Peace Corps, along with unpublished dictionaries on Brazilian and African languages, and set up several Peace Corps programs in Africa. Turner died on February 10, 1972, leaving a tremendous wealth of unpublished material from West Africa and Brazil.

Turner's greatest contribution was to rebut the assumption that there were no African retentions in the New World, using thousands of examples from all aspects of language. Turner's (1949) book paved the way for later studies in both creoles and in African American Vernacular English.

Sir Ralph Lilley Turner (IES KB MC FBA) was serving as an officer in the Gurkha Rifles during the Palestine Campaign of 1917–1918 when he conceived the plan that was to lead to *A comparative and etymological dictionary of the Nepali language* (Turner, 1931) and to *A comparative dictionary of the Indo-Aryan languages* (Turner, 1966, 1969, 1971, 1985).

Turner was born on October 5, 1888. He was introduced to Sanskrit while still at school, studied Classics and Sanskrit with comparative philology at Cambridge, and in 1913 was appointed to teach Sanskrit in Queen's College, Benares. He was, in 1920, deputed to Benares Hindu University as a professor of Indian linguistics and, in 1922, elected to the chair of Sanskrit in London University at its new School of Oriental Studies. Thus he not only influenced and worked with the rising generation of Indian historical linguists, such as S. K. Chatterji, S. M. Katre,

T. N. Dave, Baburam Saksena, etc., but was also eventually in touch with G. A. Grierson, D. L. R. Lorimer, and G. Morgenstierne, who were collecting and evaluating data from the languages of the western Himalaya and Hindu Kush.

Turner's studies of Gujarati, Sindhi, Nepali, and Gypsy Romani from 1915 to 1930 followed immediately upon the Frenchman Jules Bloch's similarly pioneering study of the evolution of Marathi. Here Turner set himself to introduce into the study of Indo-Aryan languages the Neogrammarian concept of linguistic regularity, together with a proper understanding of the phonology of accent. He was the first to give a satisfactory account of the nature and origin of Sindhi recursive consonants, and to demonstrate that the affiliations of Romani lie with Hindi, etc., rather than with the more peripheral Indo-Aryan languages.

His Nepali dictionary of 1931, listing Old, Middle, and New Indo-Aryan cognates for every word registered, became for 35 years the most indispensable and most often quoted research tool in Indian linguistic science, until superseded by his magnificent *A comparative dictionary of the Indo-Aryan languages*. Inspired by Meyer-Lübke's dictionary of the Romance languages, and originally conceived as an integral part of Grierson's *Linguistic survey of India* on which it was ultimately based, the Indo-Aryan dictionary of 1966 (in fascicles from 1962) comprised some 140,000 words arranged under nearly 15,000 Old Indo-Aryan headwords, attested in Sanskrit or provisionally reconstructed. Its timing meant that it could interact fruitfully with the compilation of Burrow and Emeneau's *Dravidian etymological dictionary* and M. Mayrhofer's *Etymologisches Wörterbuch des Altindoarischen*. Its *Phonetic analysis* (Turner, 1971) introduced into Indian lexicography the use of computer analysis. Based on the *Indexes* prepared by his wife Dorothy (Turner, 1969), that volume enabled the user to examine all words which contain a particular sound or group of sounds in any given phonetic environment. Thus the publication was completed in Turner's 83rd year, and a further volume of his *Addenda and corrigenda* (Turner, 1985) appeared posthumously.

Raw material for the Indo-Aryan dictionary had been amassed by 1937, but then Turner accepted appointment as director of the School of Oriental Studies, which, at his instigation, soon became the School of Oriental and African Studies. As the school struggled to meet the need for language training during the war, Turner's sustained campaigning led, in 1946, to a Commission of Enquiry Report that provided for the expansion and development of Oriental and African studies in London and other British universities, thus securing their future for some generations to come. On his retirement in 1957, he was at last able to edit the dictionary, and to resume a series of articles dealing with outstanding problems of historical phonology, of which the last appeared in 1982, in Turner's 94th year. He died on April 23, 1983.

Tuvalu: Language Situation

Editorial Team

© 2006 Elsevier Ltd. All rights reserved.

Tuvalu is an island nation located in the Pacific Ocean midway between Hawaii and Australia. Its name means 'Eight Standing Together' in Tuvaluan. With the exception of tiny Vatican City, it is the independent nation with the fewest inhabitants. Due to their low elevation (5 m maximum), the islands that make up this nation are threatened by any future sea level rise. The population may evacuate during the next decades to New Zealand, or Niue, a small Pacific island (independent but associated with New Zealand) that is not threatened by sea level rise, but does have decreasing population. According to the evidence of linguists, the settlement of the country goes back about 2 000 years. It is generally believed that the earlier ancestors came mostly from Samoa, possibly by way of Tokelau, while others came from Tonga and Uvea (Wallis Island). These settlers were all Polynesians with the exception of those on Nui, where many people are descendants of Micronesians from Kiribati. Formerly called the Ellice Islands, Tuvalu came under British jurisdiction in 1877 and was made part of the British Protectorate (and later colony) of the Gilbert and Ellice Islands in 1892. Tuvalu achieved full independence in 1978 and it is now a special member of the Commonwealth. The official languages of Tuvalu are Tuvaluan, a Polynesian language that is spoken by virtually everybody, and English, which is, however, not in daily use. Kiribati is a national language. There are three distinct linguistic areas in Tuvalu. The first area contains the islands of Nanumea, Niutao, and Nanumaga, where the northern variety of Tuvalu is spoken. The second linguistic group comprises the islands of Vaitupu, Nukufetau, Funafuti, and Nukulaelae, where the southern variety of Tuvalu is spoken. The third is the island of Nui, where some of the inhabitants speak a language that is fundamentally derived from I-Kiribati, a Micronesian language.

Twaddell, William Freeman (1906–1982)

J Rischel, Mahidol University, Thailand

© 2006 Elsevier Ltd. All rights reserved.

William Freeman Twaddell was born in Rye, New York on March 22, 1906, and he died in Providence, Rhode Island on March 1st, 1982. Twaddell studied German philology and earned his Ph.D. from Harvard in 1930. In 1937 he became Professor of German and chair of the German Department at the University of Wisconsin; in 1946, he received a similar post at Brown University. With his outstanding competence in general linguistics, however, he soon shifted to that field. He remained chairman of the newly established linguistics department of Brown University until his retirement in 1971. In 1953 he was president of the Linguistic Society of America, and, over the years, he became involved in numerous academic tasks, such as consultant to projects.

Twaddell's early career coincided with the upsurge of structural linguistics in the United States; he stands out as one of the most interesting scholars associated with 'Bloomfieldian' linguistics. His essay *On defining the phoneme* (1935) is generally hailed as a landmark within pregenerative phonological theory, although it did not influence the subsequent development of American structuralism as much as one might have expected. Twaddell exhibits a total independence of mind, taking issue both with Sapir's mentalism and Bloomfield's physicalism and ending up with a notion of the phoneme as 'an abstractional, fictitious unit' (thus endorsing the approach that has been dubbed 'hocus-pocus linguistics,' as against theories making a claim to reality: so-called 'God's truth linguistics'). To Twaddell, the real phonemes (or 'microphonemes') are the position-bound units that enter paradigmatic contrasts, i.e., the members of minimal

Twaddell, William Freeman (1906–1982)

J Rischel, Mahidol University, Thailand

© 2006 Elsevier Ltd. All rights reserved.

William Freeman Twaddell was born in Rye, New York on March 22, 1906, and he died in Providence, Rhode Island on March 1st, 1982. Twaddell studied German philology and earned his Ph.D. from Harvard in 1930. In 1937 he became Professor of German and chair of the German Department at the University of Wisconsin; in 1946, he received a similar post at Brown University. With his outstanding competence in general linguistics, however, he soon shifted to that field. He remained chairman of the newly established linguistics department of Brown University until his retirement in 1971. In 1953 he was president of the Linguistic Society of America, and, over the years, he became involved in numerous academic tasks, such as consultant to projects.

Twaddell's early career coincided with the upsurge of structural linguistics in the United States; he stands out as one of the most interesting scholars associated with 'Bloomfieldian' linguistics. His essay *On defining the phoneme* (1935) is generally hailed as a landmark within pregenerative phonological theory, although it did not influence the subsequent development of American structuralism as much as one might have expected. Twaddell exhibits a total independence of mind, taking issue both with Sapir's mentalism and Bloomfield's physicalism and ending up with a notion of the phoneme as 'an abstractional, fictitious unit' (thus endorsing the approach that has been dubbed 'hocus-pocus linguistics,' as against theories making a claim to reality: so-called 'God's truth linguistics'). To Twaddell, the real phonemes (or 'microphonemes') are the position-bound units that enter paradigmatic contrasts, i.e., the members of minimal

sets. Accordingly, if one uses the term phoneme in the conventional sense (the 'macrophoneme,' in Twaddell's terminology), one is referring to a fictitious class consisting of phonetically more or less similar members from different contrastive sets.

In retrospect it is clear that Twaddell's approach distances itself from the post-Bloomfieldian concept of the phoneme as a sound unit defined by distributional properties. Its anchoring in paradigmatic contrast was, on the other hand, shared by certain other versions of structuralism that were then in the making, particularly the Hjelmslevian trend.

As a philologist working on early German, Twaddell made a seminal contribution to the theoretical basis of historical linguistics by demonstrating how various major sound shifts can be understood as changes in the phonological pattern. He thus stands out as one of those who managed to establish a fruitful connection between traditional philology and structuralism.

Twaddell made significant contributions outside phonology proper. *The English verb auxiliaries* (1960) stands out as one of the highlights of descriptive English grammar from before the era when generative grammar became dominant.

Finally, it deserves mention that after moving to Brown University, Twaddell contributed substantially to the development of foreign language teaching in the United States. He worked out several textbooks dealing with the German language and introduced the use of the computer in handling text material. Nelson Francis, one of the scholars behind the *Brown standard corpus of present-day English* has explicitly acknowledged that it was inspired by Twaddell's computer-supported approach.

Twardowski, Kazimierz (1866–1938)

T P Górski, Uniwersytet Wroclawski, Wroclawski, Poland

© 2006 Elsevier Ltd. All rights reserved.

Kazimierz Twardowski was born on September 20, 1866 in Vienna. From 1866 to 1889, Twardowski studied philosophy in Vienna under Franz Brentano. In 1881 he earned his Ph.D. and, in 1894, *venia legendi* from the same University. He lectured on logics in Vienna, and worked for a short time for a Vienna insurance company. In 1895 he received the philosophy professorship at the University of Lvov, and from 1914 to 1917, he was the rector of the University of Lvov. He was also awarded the *doctor honoris causa* title by the University of Warsaw and the University of Poznań.

As the eminent professor of philosophy, Twardowski actively worked as a scholar, lecturer, and organizer. He supervised the seminar studies of many philosophers (e.g., Kazimierz Ajdukiewicz, Tadeusz Kotarbiński, Władysław Tatarkiewicz, Roman Ingarden), and also other scholars, e.g., Juliusz Kleiner (literary historian), Jerzy Kuryłowicz (linguist), Stanisław Łempicki (culture historian), and Stefan Baley (psychologist).

Twardowski's main concern was to establish a modern philosophy in Poland. He claimed that such a philosophy must not be unidirectional and so became a propagator of French and English philosophical traditions and achievements and began to develop an organizing frame for the Polish philosophy. In 1904 he established in Lvov the Polish Philosophical Society, and in 1911 realized one of his great ambitions, issuing the periodical *Ruch Filozoficzny*, which informed readers of both international philosophical issues, as well as those at home in Poland. Twardowski is also known as a promoter of the teaching of philosophy in secondary schools in the form of open lectures.

Twardowski advocated the use of scientific methods in philosophy and wanted to investigate scientific problems. At the same time, he rejected all the methods that might involve subjective opinions and, similarly to Brentano, opposed analyzing issues connected

sets. Accordingly, if one uses the term phoneme in the conventional sense (the 'macrophoneme,' in Twaddell's terminology), one is referring to a fictitious class consisting of phonetically more or less similar members from different contrastive sets.

In retrospect it is clear that Twaddell's approach distances itself from the post-Bloomfieldian concept of the phoneme as a sound unit defined by distributional properties. Its anchoring in paradigmatic contrast was, on the other hand, shared by certain other versions of structuralism that were then in the making, particularly the Hjelmslevian trend.

Kazimierz Twardowski was born on September 20, 1866 in Vienna. From 1866 to 1889, Twardowski studied philosophy in Vienna under Franz Brentano. In 1881 he earned his Ph.D. and, in 1894, *venia legendi* from the same University. He lectured on logics in Vienna, and worked for a short time for a Vienna insurance company. In 1895 he received the philosophy professorship at the University of Lvov, and from 1914 to 1917, he was the rector of the University of Lvov. He was also awarded the *doctor honoris causa* title by the University of Warsaw and the University of Poznań.

As the eminent professor of philosophy, Twardowski actively worked as a scholar, lecturer, and organizer. He supervised the seminar studies of many philosophers (e.g., Kazimierz Ajdukiewicz, Tadeusz Kotarbiński, Władysław Tatarkiewicz, Roman Ingarden), and also other scholars, e.g., Juliusz Kleiner (literary historian), Jerzy Kuryłowicz (linguist), Stanisław Łempicki (culture historian), and Stefan Baley (psychologist).

Twardowski's main concern was to establish a modern philosophy in Poland. He claimed that such a philosophy must not be unidirectional and so became a propagator of French and English philosophical traditions and achievements and began to develop an organizing frame for the Polish philosophy. In 1904 he established in Lvov the Polish Philosophical Society, and in 1911 realized one of his great ambitions, issuing the periodical *Ruch Filozoficzny*, which informed readers of both international philosophical issues, as well as those at home in Poland. Twardowski is also known as a promoter of the teaching of philosophy in secondary schools in the form of open lectures.

Twardowski advocated the use of scientific methods in philosophy and wanted to investigate scientific problems. At the same time, he rejected all the methods that might involve subjective opinions and, similarly to Brentano, opposed analyzing issues connected

with one's viewpoint. He claimed that philosophy is the theory of science, the subject of which is the study of human cognition. Thus, he supplemented his researches with psychological evidence and data now referred to as semantic. Twardowski divided the cognitive psychical phenomena into **representations** and **statements**; the former into **images** and **conceptions**. According to this distinction, representation is not an element of a statement, but a necessary condition of it (idiogenetic theory of statements). For example, the conception of a rectangle consists of an image of some plain geometric figure that the agent complements with another two characteristics: rectangular and equilateral.

Apart from investigating purely scientific problems, Twardowski cultivated a rule of clear speaking according to his saying, 'the one who speaks unclearly, thinks unclearly,' in which he always called for proofs of every statement and avoided speculations. Later, his students formed the Warsaw-Lvov School of Philosophy, and, since they followed Twardowski's ideas, it was a school of analytic philosophy. Twardowski died on February 12, 1938 in Lvov.

20th-Century Linguistics: Overview of Trends

G Graffi, University of Verona, Verona, Italy

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Two theoretical trends can be considered as hallmarks of 20th-century linguistics: structural linguistics and generative grammar. They almost equally divide this epoch: structural linguistics (or, shortly, structuralism) flourished between the 1910s and the 1950s, generative grammar from the 1950s. Structuralism was not a unitary theory, but rather a galaxy of schools sharing some principles; furthermore, some important differences distinguish European structuralist schools from the American one. Generative grammar, instead, originated as a unitary theory, which subsequently divided into different schools and which stimulated several alternatives from scholars not accepting it.

Both structural linguistics and generative grammar also had an impact outside linguistics: between the 1950s and 1970s (especially in France), the former became the model for all humanities, hence a 'structural' anthropology, a 'structural' sociology, etc., were developed. Generative grammar, in its turn, was seen as one of the initial steps of the so-called cognitive revolution. Neither of these extensions was free of problems: in many cases, concepts of structural linguistics were applied to other fields with some illegitimate modifications, and the debate on what 'cognitive' really means has not yet come to a solution. All this, however, does not lessen the outstanding role of both structuralism and generative grammar within 20th-century linguistics and within 20th-century thought in general. This article will therefore focus almost exclusively on these two theoretical trends: even sociolinguistics will be dealt with rather as an alternative to generative grammar rather

Two-Dimensional Semantics

C Spencer, Howard University, Washington, DC, USA

© 2006 Elsevier Ltd. All rights reserved.

When we ask whether a sentence is true or false, we are always asking with respect to a particular world. We are typically concerned about a sentence's truth value in the actual world, but we sometimes consider its truth value in other possible worlds as well. Thus the evaluation of any sentence is world-dependent in the sense that whether it is true (in a world) depends on the facts about that world. Context-sensitive sentences are also world-dependent in another quite different sense – what they mean depends on facts about the context, or world, in which they are used. For instance, *it's cold here* uttered in Pakistan means that it is cold in Pakistan, and when uttered in New Jersey means that it is cold in New Jersey. Two-dimensional semantics uses a formal apparatus from two-dimensional modal logic to characterize these two kinds of world-dependence. The two-dimensional framework has been applied to a variety of problems in semantics (indexicals and demonstratives and their interaction with modal operators), pragmatics (presupposition), and philosophy (accounts of the *a priori/a posteriori* distinction and the psychological/functional roles of thought). All of these applications depend on various assumptions, which are not implicit in two-dimensional modal logic, and many of which are controversial.

Modal logic allows that expressions may have different extensions in different possible worlds. For instance, it allows that the objects that satisfy a predicate in one world may differ from those that satisfy it in another. In one-dimensional modal logic, the rule that determines each expression's extension in every world, called its intension, is represented as a function from possible worlds into extensions. The intension of a predicate F, for instance, is a function that takes a possible world onto the set of individuals that satisfy F in that world, and the intension of a singular term t is a function taking possible worlds to single individuals. Two-dimensional modal logic allows that a single expression may be associated with different one-dimensional intensions in different contexts, or worlds, of use. So it associates a two-dimensional intension with each expression, which is a function from possible worlds to one-dimensional intensions, or equivalently a function from ordered pairs of possible worlds into extensions (see Segerberg, 1973; Aqvist, 1973; van Fraassen, 1977 for expositions of a two-dimensional modal semantics for formal languages).

Since a two-dimensional intension takes pairs of possible worlds onto extensions, it has the resources to represent the two different kinds of world-dependence mentioned above. One of the worlds supplies the contextual elements needed to interpret context-sensitive expressions, and the other world supplies the context of evaluation. I will call the entity that plays the former role the world of occurrence, and the entity that plays the latter role the world of evaluation, although no terminology is standard.

Two-dimensional intensions can be represented in a matrix such as Figure 1, which gives a two-dimensional intension for a single expression, s. In the leftmost column of Figure 1, w^1, w^2, and w^3 represent possible worlds considered as worlds of occurrence. In the top row, these same three worlds are considered as worlds of evaluation. Suppose that s is the sentence *I am in San Francisco*. In w^1, Ann is the speaker of this sentence and Ann is in San Francisco. She is also in San Francisco in w^3, but not in w^2. In w^2, Beth is the speaker, but she is in London in all three worlds. In w^3, Carl is the speaker, and Carl is in San Francisco in all three worlds. The cells of this matrix are filled in with truth values, since this is the appropriate extension for sentences. The row corresponding to w^1 tells us the truth value, in w^1, w^2, and w^3, of the sentence s, considered as occurring in w^1. In w^1, Ann utters this sentence, so it is true just in the case where Ann is in San Francisco. Accordingly, this occurrence is true in w^1 and w^3, but false in w^2, as the matrix indicates. Similarly, the row

s	w^1	w^2	w^3
w^1	T	F	T
w^2	F	F	F
w^3	T	T	T

Figure 1 Two-dimensional matrix.

corresponding to w^2 tells us the truth value in these three worlds of the sentence *s*, now considered as occurring in w^2. Since Beth, not Ann, utters *s* in w^2, this occurrence is true just in the case where Beth is in San Francisco. Since she is in London in all three worlds, the matrix contains an F in every cell in this row. The third row of the matrix tells us that the sentence *s*, considered as occurring in w^3, is true in all three worlds. Since Carl is the speaker in w^3, and he is in San Francisco in all three worlds, the row contains a T in every cell.

The matrix in Figure 1 only contains three possible worlds. But it is in principle possible to construct more comprehensive matrices, which contain many or all possible worlds. When the associated expression is a sentence, these more comprehensive matrices determine a number of propositions of theoretical interest. First, each row in such a matrix specifies a set of worlds in which the sentence *s* expresses a truth when it occurs in the world of that row. When the row in question is that corresponding to the actual world, the proposition it determines is the proposition *s* expresses. Another proposition of some theoretical interest is the set of worlds *w* in which the occurrence of *s* in *w* expresses a truth in *w*. If the matrix is constructed so that worlds w–w^n are arranged in numerical order on the top row and down the leftmost column, this proposition will be the diagonal of the matrix.

Applications

Different philosophers have modified this basic application of the two-dimensional framework in different ways for different purposes in semantics, pragmatics, philosophy of mind and language, and epistemology. Some philosophers follow the model of two-dimensional modal logic and offer a two-dimensional semantics for expressions (Kaplan, 1989). Others apply the two-dimensional apparatus to utterances (Stalnaker, 1978), or thoughts (Chalmers, 1996; Jackson, 1998) instead of or in addition to expressions themselves. Philosophers have also interpreted what I have called the world of occurrence and world of evaluation in different ways. Some construe both as possible worlds (Stalnaker, 1978). For others, they are ordered n-tuples of contextually supplied elements (Kaplan, 1989) or maximal epistemic possibilities (Chalmers, 2004). Some philosophers think that the worlds of evaluation and worlds of occurrence are the same type of entity, and for others, different kinds of entities play the roles of worlds of utterance and worlds of evaluation within the same application of the two-dimensional framework (Kaplan, 1989; Chalmers, 1996, 2004).

David Kaplan has used the two-dimensional framework to provide a semantics for indexical and demonstrative pronouns. For Kaplan, indexicals and demonstratives are associated with characters, which are rules that determine their contents in different contexts of use. For instance, the character of *I* is the rule that says that an occurrence of *I* in a world of occurrence *w* refers to the speaker of that world of occurrence, and this individual is the content of this occurrence of *I*. Kaplan identifies worlds of occurrence (which he calls contexts of use) and worlds of evaluation (which he calls circumstances of evaluation) as ordered n-tuples of a speaker, time, location, and world.

Robert Stalnaker has suggested that the two-dimensional framework can explain how utterances acquire pragmatic effects. A pragmatic effect of an utterance is something that the utterance conveys beyond its semantic content, and which is determined both by the sentence uttered and the conversational context in which the utterance takes place. The conversational context supplies what Stalnaker calls a context set, which contains all beliefs and assumptions mutually held by all parties to the conversation, and against which the utterance is interpreted. Stalnaker proposes that we construct a two-dimensional matrix for a specific utterance and include in the matrix all and only those worlds in the context set. Typically, an utterance will express the same proposition in every world in the context set, because this set includes information about what the expressions in the utterance mean, how context-sensitive terms are to be interpreted, and which objects they refer to. However, in some cases the context set will not include all of this information, so that the utterance will express different propositions in different worlds. For instance, consider an utterance of *I am Bill Clinton*. This utterance either expresses or a necessarily true proposition, if the speaker is in fact Bill Clinton, or a necessarily false proposition otherwise. In neither case would the literal content of this utterance serve the typical purpose of ruling out some possibilities that the preceding parts of the conversation had left open. Yet the utterance can serve this typical purpose if some participants in the conversation do not already know who the speaker is. In such cases, the context set for the conversation will include worlds in which the speaker is Bill Clinton, and worlds in which he is someone else. Thus the speaker's utterance of *I am Bill Clinton* expresses different propositions in different worlds in the context set. Which of these is the one the utterance conveys? Stalnaker suggests that it may be the diagonal of the two-dimensional matrix associated with this

utterance. This is the contingent proposition that the speaker of a particular utterance is Bill Clinton, and this is intuitively the information conveyed by this utterance.

Stalnaker and Kaplan, among other philosophers, have also suggested that the two-dimensional framework does some strictly philosophical work. First, it appears to offer some account of the special epistemic properties of sentences like (1) (Kaplan, 1989; Stalnaker, 1978; but see Stalnaker, 2004).

(1) *I am here now.*

Uses of (1) express contingent truths, but (1) expresses a truth in every world of use. So (1) is in a certain sense an *a priori* truth – one need not know anything about the world of use to know that (1) expresses a truth in it. Although the different propositions it expresses in different worlds are all contingent, the diagonal of the two-dimensional matrix it determines will be necessary.

Martin Davies and Lloyd Humberstone have also applied the two-dimensional framework to a similar end, to explain a distinction between superficial and deep contingency earlier introduced by Gareth Evans. (Davies and Humberstone, 1980; Evans, 1979). Evans claimed that a sentence *s* is superficially contingent if and only if there exists a world *w* such that it is not the case that *s* is true in *w*, and *s* is deeply contingent if its truth depends on a contingent feature of the actual world. Typically, deep and superficial necessity coincide, but Evans argues that they need not always do so. Evans introduced this distinction to criticize Saul Kripke's claim that some propositions, such as (2) are both contingent and *a priori*.

(2) *The standard meter stick in Paris is one meter long.*

(2) is contingent because that very stick might have been less than one meter, but *a priori* because one can know (2) without appeal to experience. Evans argued that in all putative cases of the contingent *a priori*, the two notions of contingency come apart, and all such cases are merely superficially contingent. Davies and Humberstone apply Evans's basic distinction to necessity rather than contingency, and claim that a statement *s* is deeply necessary if and only if the diagonal of the two-dimensional matrix for *s* contains every possible world, and it is superficially necessary if and only if the horizontal of the matrix for the row corresponding to the actual world contains every possible world. They do not attempt to use the two-dimensional framework to characterize *a priority* directly, though they do note that they know of no examples of *a priori* truths that are not deeply necessary. Since they also acknowledge some examples of deeply necessary *a posteriori* truth, they do not identify deep necessity, in their sense, with *a priority*.

David Chalmers and Frank Jackson have made the more ambitious identification of necessity on the diagonal with *a priority* (Chalmers, 1996; Jackson, 1998). Jackson in particular has suggested that there is only one notion of necessity and that the deep necessity Davies and Humberstone have defined is really *a priority* in disguise. For Chalmers and Jackson, thoughts as well as sentences have two-dimensional intensions, which they understand as functions from ordered pairs of centered worlds and uncentered worlds to truth values. A centered world is just a possible world with an individual and a time marked as its center. This two-dimensional intension determines both a primary and a secondary intension. The primary intension of a thought or sentence token *t* is a set of centered worlds *w* in which *t*, considered as occurring in *w*, is true in *w*, and would be found along the diagonal of a two-dimensional matrix. Its secondary intension is a set of uncentered worlds *w* in which *t*, considered as occurring in the actual world, is true in *w*, and would be found along the horizontal row associated with the actual world in a two-dimensional matrix. Chalmers and Jackson argue that primary intensions provide the following robust characterization of *a priori* knowledge: a thought is *a priori* if and only if its primary intension is necessary, that is, it contains every centered world (Jackson, 1998; Chalmers, 2004). Critics have attacked their view for what they see to be its revival of descriptivism about reference and its commitment to internalism about content (Soames, 2005; Byrne and Pryor, forthcoming; Stalnaker, 2004). Although Chalmers and Jackson embrace internalism about thought content, they deny that their application of two-dimensional semantics commits them to descriptivism.

Tyndale, William (1494–1536)

M Garcarz, University of Warsaw, Warsaw, Poland

© 2006 Elsevier Ltd. All rights reserved.

William Tyndale – English humanist, biblical translator, martyr – was born near the border of Wales, probably in Gloucestershire, in 1494 or 1495. He grew up in Oxford where, in 1515, he graduated from Oxford University. Later he moved to Cambridge where he met Erasmus, the theologian who influenced young Tyndale. In 1521, he was ordained into the priesthood, and in the same year, he became a chaplain in the house of Sir John Walsh.

Tyndale, who tried to make the first English translation of *Enchiridion*, devoted himself to the study of the Scriptures, which was viewed as an open commitment to the doctrines of the Reformation. As a consequence, he was summoned before the chancellor of the diocese of Worcester who charged him with heresy. As an avid adherent to reforming the Church, Tyndale became obsessed with the idea of addressing the English translation of the Bible to simple people, writing it in the common English language. To spread his views, Tyndale traveled from town to town, presenting his ideas to the common people of England. The church authorities were most displeased with Tyndale's inspirations and persecuted him. Finally, in 1524, Tyndale left England under a false name.

In the same year he met Martin Luther at Wittenberg, where he consulted him on the Bible translations. The first English translation of the New Testament was completed in August, 1525. Tyndale was indeed a gifted scholar and a translator. He knew Greek, Hebrew, and seven other languages. Tyndale's Old and New Testament were actually the first English translations of the Scriptures directly from the Greek and Hebrew languages. The printing began at Cologne in the summer of 1525 and was completed at Worms.

In the following year, some copies of Tyndale's translation of the New Testament were smuggled into England, where they began to circulate among the common folk. Tyndale already had powerful enemies in England, as well as on the Continent. In Antwerp he had theological arguments with Sir Thomas More, a fervent opponent of Luther's Reformation. The Church authorities acted immediately, and, in the end, Tyndale was betrayed by one of his own students (Henry Phillips). Captured and arrested in 1535, he was tried for heresy and treason and was hung and burned at the stake. He died a martyr's death on October 6, 1536 in Vilvorde in Belgium.

The first complete English translation of the Holy Bible was published on the Continent in 1535. With the decree of King Henry VIII, the first Tyndale translation of the New Testament was officially printed in England in 1536. Tyndale laid the foundation for further English translations of the Bible. The fully authorized and

Type versus Token

L Wetzel, Georgetown University, Washington, D.C., USA

© 2006 Elsevier Ltd. All rights reserved.

The Distinction

The distinction between a 'type' of thing and a 'token' of that type of thing, first described in those terms by C. S. Peirce, is an ontological one, akin to the universal/particular distinction (but arguably different from it; see below). Peirce pointed out that English, unlike German, has only one definite article, the word 'the'; this is the word type. Yet pick up any book in English and quite a few words on a particular page are apt to be 'the's; these are word tokens. Word tokens are concrete; they are spatiotemporal particulars such as inscriptions composed of ink, raised dots, light pixels, or utterances of phonetic sounds, or smoke signals, dots and dashes, etc. (Although not every sequence of three dots followed by three dashes followed by three dots, e.g., is a token of the Morse code distress signal; it may need to have been produced with a certain intention and in accordance with certain conventions. *see* **Speech Acts**.) Each token has a unique spatiotemporal location, unlike a type, which is arguably an abstract object and does not.

In other words, the word 'word' is ambiguous. When we read that there are one million words in the *O.E.D.*, that Shakespeare's vocabulary consisted of 30 000 words, or that a two-year old should be able to say 20 words, we are to count word **types**. If the printer warns us to replace the ink cartridge every 100 000 words, we are to count word **tokens**. Different counting procedures point to different criteria of identity associated with the word 'word.' The same may be said of letters, phonemes, sentences, and most other linguistic items. There are only 26 letters in the English alphabet, yet there are more than 26 letters in (your concrete token of) this sentence. The former are types, the latter tokens. There are 44 phonemes in English, yet millions of phonemes uttered every day. The numbers reverse when it comes to sentences, for linguists assure us that there are many more, perhaps infinitely many more, sentence types than token sentences produced. The type-token distinction explains and is motivated by such considerations. It helps us to avoid fallacious inferences such as that if Shakespeare knew 30 000 words, then the total number of words in my copy of Shakespeare's plays cannot exceed 30 000. (For more about words types, see Wetzel (2000).)

Its Usefulness

The type-token distinction is important to other branches of philosophy besides philosophy of language and logic. In philosophy of mind, it yields two significantly different versions of the identity theory: one identifies types of mental events with types of physical events (suggesting that the best way to understand mental activity is through neurology); the other merely says that every mental event is some physical event or other (but not necessarily a biological physical event, leaving the door open to an understanding of mental activity in terms of, say, programming) (see Block, 1980). In aesthetics, it is customary to distinguish works of art such as Mozart's Prague symphony (a type) from its many actual performances (tokens) (and also from its many interpretations, recordings, playings of recording, etc.) (see Wollheim, 1968; Wolterstorff, 1975). In ethics, actions are said to be right/wrong, but there is a dispute as to whether there are general principles that prescribe which types of actions are right/wrong or no general principles and only action tokens that are right/wrong.

Outside of philosophy, type talk is ubiquitous. That is, in scientific and everyday discourse we often speak

The Distinction

The distinction between a 'type' of thing and a 'token' of that type of thing, first described in those terms by C. S. Peirce, is an ontological one, akin to the universal/particular distinction (but arguably different from it; see below). Peirce pointed out that English, unlike German, has only one definite article, the word 'the'; this is the word type. Yet pick up any book in English and quite a few words on a particular page are apt to be 'the's; these are word tokens. Word tokens are concrete; they are spatiotemporal particulars such as inscriptions composed of ink, raised dots, light pixels, or utterances of phonetic sounds, or smoke signals, dots and dashes, etc. (Although not every sequence of three dots followed by three dashes followed by three dots, e.g., is a token of the Morse code distress signal; it may need to have been produced with a certain intention and in accordance with certain conventions. *see* **Speech Acts**.) Each token has a unique spatiotemporal location, unlike a type, which is arguably an abstract object and does not.

In other words, the word 'word' is ambiguous. When we read that there are one million words in the *O.E.D.*, that Shakespeare's vocabulary consisted of 30 000 words, or that a two-year old should be able to say 20 words, we are to count word **types**. If the printer warns us to replace the ink cartridge every 100 000 words, we are to count word **tokens**. Different counting procedures point to different criteria of identity associated with the word 'word.' The same may be said of letters, phonemes, sentences, and most other linguistic items. There are only 26 letters in the English alphabet, yet there are more than 26 letters in (your concrete token of) this sentence. The former are types, the latter tokens. There are 44 phonemes in English, yet millions of phonemes uttered every day. The numbers reverse when it comes to sentences, for linguists assure us that there are many more, perhaps infinitely many more, sentence types than token sentences produced. The type-token distinction explains and is motivated by such considerations. It helps us to avoid fallacious inferences such as that if Shakespeare knew 30 000 words, then the total number of words in my copy of Shakespeare's plays cannot exceed 30 000. (For more about words types, see Wetzel (2000).)

Its Usefulness

The type-token distinction is important to other branches of philosophy besides philosophy of language and logic. In philosophy of mind, it yields two significantly different versions of the identity theory: one identifies types of mental events with types of physical events (suggesting that the best way to understand mental activity is through neurology); the other merely says that every mental event is some physical event or other (but not necessarily a biological physical event, leaving the door open to an understanding of mental activity in terms of, say, programming) (see Block, 1980). In aesthetics, it is customary to distinguish works of art such as Mozart's Prague symphony (a type) from its many actual performances (tokens) (and also from its many interpretations, recordings, playings of recording, etc.) (see Wollheim, 1968; Wolterstorff, 1975). In ethics, actions are said to be right/wrong, but there is a dispute as to whether there are general principles that prescribe which types of actions are right/wrong or no general principles and only action tokens that are right/wrong.

Outside of philosophy, type talk is ubiquitous. That is, in scientific and everyday discourse we often speak

in ways that apparently refer to types. When, for example, we read that the mountain lion disappeared from Iowa in 1867, but now is making a comeback there in the suburbs, we know no particular cat disappeared; rather, a type of cat, a species, did so. Similarly, to say the ivory-billed woodpecker is extinct, or that the banded bog skimmer is rare is not to be referring to one particular organism. The first gene that scientists found linked to an ordinary human personality trait (novelty seeking) is obviously a type of gene. These are examples of sentences where a **singular term** apparently refers to a type. But we also **quantify** over types with great regularity, as when a study claims that of 20 481 species examined, two-thirds were secure, 7% were critically imperiled, and 15% were vulnerable. Often we do both, as when it was claimed (in the 60s) that there are 30 particles, yet all but the electron, neutrino, photon, graviton, and proton are unstable. As with art (above), so with artifacts: when we read that the personal computer is more than 30 years old and is only now beginning to reveal its true potential, we do not think there is a particular dusty 30-year-old PC that is somehow improving. The chess move, we are told, of accepting the Queen's Gambit with 2...dc has been known since 1512, but Black must be careful in this opening – the pawn snatch is too risky. For a comprehensive treatment of reference to the many sorts of abstract objects we make in discourse, see Asher (1993).

Universals

The type-token distinction is akin to the universal-particular distinction, but there is some question as to whether types ought to be classified with the classic property examples of universals such as *being white*. If the hallmark of a universal is a capacity to have more than one instance, then types are universals. Types are generally also said to be abstract, just as universals are often said to be, in contrast to their tokens, which are concrete. However, if the hallmark of a universal is to answer to a predicate or open sentence the way *being white* answers to 'is white,' then types do not resemble universals, as they answer to singular terms (and quantifiers). This is amply illustrated in the preceding paragraph. That is to say, types seem to be *objects*, like numbers and sets, rather than properties or concepts; it's just that they are not particular concrete objects. If, then, we follow Frege (1977) in classifying all objects as complete and saturated and referred to by singular terms, and all properties as incomplete and unsaturated and referred to by predicates, then types would not fall into the same category as the classic examples of universals such as *being white*.

A Related Distinction

The type-token distinction may seem to license or encourage the following fallacious inference: This encyclopedia entry consists of (about) 2,000 words. Word types, or word tokens? It can't be word types, since my editor assures me that each and every 'the' counts as another word. Therefore it consists of (about) 2,000 word tokens. But then the encyclopedia entry itself would be a token – which it is not. (It is not the one in the Library of Congress in Washington, for example, as opposed to the one in the Bibliothèque Nationale in Paris.) The entry itself has many tokens, but is itself a type. As Simons (1982) points out, since it is abstract, it cannot be composed of concrete word tokens. So what are we counting when we count 2000 words? **Occurrences** of word types (see Wetzel (1993), for an account). That is to say, the word 'the' occurs quite a few times in this encyclopedia entry. The letter 'x' occurs three times in the formula '$(\exists x)$ (Gx & Hx)'. Now this may seem impossible; how can one and the same thing occur more than once in something without there being two tokens of it? See Armstrong (1986) and Lewis (1986a), (1986b) for a debate on this point, and Wetzel (2006) for a rebuttal of Lewis. However, consider a sequence. The number 1 – the very same number – occurs several times in the sequence $<0,1,0,1,0,1>$. Even a concrete object can occur more than once. The same person occurs more than once in the sequence of New Jersey million dollar lottery winners, remarkably enough. The moral is that not every occurrence of a type is a token of it.

Do Types Exist?

Obviously, if types are universals then whether they exist is a matter of debate – a debate that goes back at least to Plato. Modern Platonists say they exist as transcendent abstract objects with no space-time location; see Bromberger (1989), Hale (1990), Katz (1981), and Wetzel (2002). Aristotelian realists say they exist as repeatable objects with numerous space-time locations; see Armstrong (1978), Wollheim (1968), and perhaps Zemach (1992) – although he calls himself a nominalist. Nominalists say they don't exist; see Goodman and Quine (1947), Quine (1953), Goodman (1977), and Bromberger (1992). With respect to universals, there is a third position, conceptualism, which tries to make do with mental objects such as ideas, or representations, in lieu of abstract ones, but since ideas also come in types and tokens, conceptualism only postpones the question – although see Sźabo (1999). Some nominalists believe that if types are abstract objects, then, as is true for

all abstract objects, we cannot have knowledge of them, because we cannot causally interact with them. Others take issue with a traditional argument for universals, according to which a red sunset and a red rose have something in common, and this something can only be the property of *being red*, so properties exist. Quine (1953), for example, objects that 'the rose is red because the rose partakes of redness' is uninformative – we are no better off in terms of explanatory power with such extra objects as *redness* than we are without them; perhaps a rose's being red and a sunset's being red are just brute facts.

Since Quine's attack on the traditional argument convinced many that that argument fails, the debate has shifted away from predicates. A realist nowadays is better off pointing to the fact, evidenced in the first four paragraphs above, that we talk as if there are types (even without appealing to predicates). That is, we frequently use singular terms for types, and we quantify over types in our theories. Quine (1953) has rightly stressed that we are ontologically committed to that over which we quantify. (For these reasons, although he rejected *redness,* Quine (1987: 217) held that expression types such as the word 'red' exist.) As we saw, Frege emphasized that singular term usage is in indicator of **objecthood**. Since at least on the face of it we are committed to types in many fields of inquiry, it is incumbent upon the nominalist to 'analyze them away.' (Or to maintain that all theories that appear to refer to types are false – but this is a radical approach, as it comprises nearly all theories.)

The usual nominalist approach is to maintain that the surface grammar of type talk is misleading, that talk of types is just a harmless way of talking about tokens (see Bromberger, 1992). To say 'the horse is a mammal' is just to say 'all horses are mammals,' for example. The idea is to 'analyze away' apparent references to types by offering translations that are apparently type-free and otherwise nominalistically acceptable (see Goodman and Quine (1947) and Goodman (1977) for optimism). The problem is how to do this for each and every type reference (see Wetzel (2000) for pessimism). Sometimes the translation is obvious as with the horse example, where the predicate 'is a mammal' is true of the type and true of all the tokens too. But not all predicates are so cooperative. The grizzly bear is ferocious, but not every grizzly is ferocious. The word 'Gluck' is guttural, but its token inscriptions are not. For that matter, the written tokens have nothing observable in common with spoken tokens (if there is no type). Collective properties pose even more of a challenge. 'The ivory-billed woodpecker is extinct' is perhaps approximately equivalent to 'there are no more ivory-billed woodpeckers, although there used to be interbreeding populations of them,' which is arguably nominalistic. But it is very difficult to find a nominalistic paraphrase for 'Old Glory had 28 stars in 1846 but now has 50.' And it is nigh-on impossible to find a paraphrase for the claim mentioned above, that 'Of 20 481 species examined, two-thirds were secure, 7% were critically imperiled, and 15% were vulnerable.'

But the clincher for this nominalistic proposal (that all type-talk can be analyzed away in favor of talk of tokens) is that it presupposes that all types have tokens. Whether all types have tokens is a matter of some debate. Peirce, for example claimed it, but Chomsky (1957) denied it. It would violate laws of syntax that together have the consequence that there are more sentences than have been or will be instantiated.

Typography

R Bringhurst, Heriot Bay, Canada

© 2006 Elsevier Ltd. All rights reserved.

Typography is the art of formalizing written text for replication. In some significant respects, therefore, typography is to writing as writing is to speech: a way of picking and drying the flowers of language that would otherwise be all too quickly gone. Like writing, however, typography has led to the cultivation of new varieties of language – often unspoken and sometimes unspeakable – which are exclusively intended for preservation in visible form. In theory, instances of language are chosen for preservation – first in writing, then in type – on the basis of their merits. In practice, much language is typographically preserved because that is the only form in which it was ever intended to function.

'Type' is from Greek τύπος, a casting or impression, from τύπτειν, to strike or beat. 'Typography' originally meant to copy out (γράφειν) a text mechanically, using sculpted, cast replicas of handwritten letters. When the term 'typographia' was coined, in Italy toward the end of the 15th century, the reigning method of text printing was letterpress, a three-dimensional process giving a subtly three-dimensional result. Since the mid 20th century, however, most printing has been two-dimensional. 'Type' to the typographer now means reusable, prefabricated letters in any functional medium (from three-dimensional metal to zero-dimensional digital information) and the mostly two-dimensional printed traces that they leave.

Typography embraces the creation of these letters and preparation of their context as well as their actual use. One of its major subdivisions, therefore, is type design: the shaping of individual letterforms, their companion diacritics, punctuation, numerals, and other symbols, and the arrangement of these glyphs into working sets, called fonts. The rest of the field – covered by the French terms *mise en texte* and *mise en page* – involves the selection of type, paper, and ink; the typographic styling of written texts (which comes down in large part to decisions about headings, textual subdivisions, and style of punctuation); the design and organization of empty pages (determining folds, trimming, and binding); and the translation of text into visible patterns and structures with which those empty pages may be filled.

The craft has long been known as 'the black art,' as if ink were the key to it all, but one of the working principles of typography, as of calligraphy and painting, is that the negative space matters no less than the positive. Typographers therefore concern themselves with the sizes and shapes of the spaces (known as counters) inside letters, the spaces between letters and words, the spaces between lines (known as leading), and with the margins surrounding the textblock, as much as with the ink-bearing areas themselves. (See **Figures 1** and **2**.)

Type is normally measured by body size – the height of the real or imaginary block on which the ink-bearing image of the letter is or could be cast. But the size of this type body alone tells us little about the trace it will leave on the page. The typographer will be more concerned with other factors, most of which can be

Typography is the art of formalizing written text for replication. In some significant respects, therefore, typography is to writing as writing is to speech: a way of picking and drying the flowers of language that would otherwise be all too quickly gone. Like writing, however, typography has led to the cultivation of new varieties of language – often unspoken and sometimes unspeakable – which are exclusively intended for preservation in visible form. In theory, instances of language are chosen for preservation – first in writing, then in type – on the basis of their merits. In practice, much language is typographically preserved because that is the only form in which it was ever intended to function.

'Type' is from Greek τύπος, a casting or impression, from τύπτειν, to strike or beat. 'Typography' originally meant to copy out (γράφειν) a text mechanically, using sculpted, cast replicas of handwritten letters. When the term 'typographia' was coined, in Italy toward the end of the 15th century, the reigning method of text printing was letterpress, a three-dimensional process giving a subtly three-dimensional result. Since the mid 20th century, however, most printing has been two-dimensional. 'Type' to the typographer now means reusable, prefabricated letters in any functional medium (from three-dimensional metal to zero-dimensional digital information) and the mostly two-dimensional printed traces that they leave.

Typography embraces the creation of these letters and preparation of their context as well as their actual use. One of its major subdivisions, therefore, is type design: the shaping of individual letterforms, their companion diacritics, punctuation, numerals, and other symbols, and the arrangement of these glyphs into working sets, called fonts. The rest of the field – covered by the French terms *mise en texte* and *mise en page* – involves the selection of type, paper, and ink; the typographic styling of written texts (which comes down in large part to decisions about headings, textual subdivisions, and style of punctuation); the design and organization of empty pages (determining folds, trimming, and binding); and the translation of text into visible patterns and structures with which those empty pages may be filled.

The craft has long been known as 'the black art,' as if ink were the key to it all, but one of the working principles of typography, as of calligraphy and painting, is that the negative space matters no less than the positive. Typographers therefore concern themselves with the sizes and shapes of the spaces (known as counters) inside letters, the spaces between letters and words, the spaces between lines (known as leading), and with the margins surrounding the textblock, as much as with the ink-bearing areas themselves. (See **Figures 1** and **2**.)

Type is normally measured by body size – the height of the real or imaginary block on which the ink-bearing image of the letter is or could be cast. But the size of this type body alone tells us little about the trace it will leave on the page. The typographer will be more concerned with other factors, most of which can be

Figure 1 The measurement of type. *Type size* or *body size* is the height of the face of the block on which the letter is carried – or *would be carried* if it were cast as metal type. *Line height* (also known as *leading*) equals *type size* plus *lead*, but it is customarily measured from baseline to baseline. The *cap height* may or may not match the height of the ascenders. Letterspacing *increases* space between letters; kerning *decreases* it. With metal type, letterspacing is easy but kerning is more difficult. With digital type, both are equally easy.

Figure 2 A piece of foundry type. (After Chappell & Bringhurst, 1999.)

expressed in terms of relative proportions. These factors include (1) the relative darkness or lightness and wideness or narrowness of the letters, (2) the degree of internal contrast (relation of thin strokes to thick strokes), (3) the implicit axis of the letters (i.e., the implied rotational posture of the writing hand), (4) the presence or absence and relative prominence of the serifs, (5) the crispness or bluntness of serifs or stroke ends, (6) the aperture (relative openness of semi-enclosed forms such as c, e, and s), (7) the relative size of upper and lower case (in typographic terms, the relation of cap-height to x-height and height of ascenders), (8) the internal proportions of the lower case (relations of x-height to ascender and descender), (9) the tightness of the set (which is to say, the amount of space, on average, between letters), (10) in digital type, the quality of the kerning table (a built-in set of instructions for tightening or loosening the spacing of selected pairs of glyphs), (11) the average size of the spaces between words in relation to the darkness of the face and the fit of contiguous letters, (12) the relation of type size to line-length or measure (often expressed in the average number of characters per line), (13) the relation of cap-height and x-height to interlinear space, (14) the inherent proportions of the textblock (relation of height to width), (15) the relation of the textblock to the page (in other words, the proportions of the margins to each other and to the textblock), and not least (16) the historical and social connotations of the typeface.

As this list may suggest, typographers tend to focus their attention on the letter and the page, where writers are apt to concentrate on the lexeme and the sentence, and speakers on the morpheme, phrase, and clause. This is a sign that typographers may in fact lose sight of language in the very act of translating it into a durable visual form. Yet typography is a natural outgrowth of writing. It is a bridge between visual art and textual editing, and, together with writing and editing, part of a bridge between the things that humans say and the tangible traces they leave behind.

In some aspects of their work, however, typographers do indeed push writing past the realm of language, into the realm of iconic visual symbols. Commercial logotypes exemplify this kind of supra- or sub-linguistic typography.

None of the subtleties of concern to a typographer is openly expressed in a conventional type specification, which usually consists of a name and three numbers. For example: Palatino roman 9/11 × 16. Even this description, though straightforward and precise, gives varying results depending on where the fonts originate and which system of measurement is employed. 'Palatino roman' is the name of a type, designed by Hermann Zapf in 1946, but it has been legitimately made in several different versions and illegitimately copied by many different firms. Professional typographers are also prone to edit their digital fonts, introducing further small refinements. Thus not all incarnations of Palatino roman are identical. As for the numbers: in most of the Anglo-American world, 9/11 × 16 means type in the 9-point body size, set with 2 points additional leading ($9 + 2 = 11$ points vertical distance from baseline to baseline), on a horizontal measure (line length) of 16 picas. A pica is, in metal type, 0.16608 inch (4.21844 mm) or, in digital type, exactly one sixth of an inch (4.23334 mm), and there are 12 points in a pica. In much of Europe,

however, the units employed are the cicero and its subdivision, the Didot point. These are roughly 7% larger than the pica and Anglo-American point. Depending on the measurement system used, therefore, there may be 72.25, exactly 72, or only 67.4 points per inch.

Early experiments with cutting and casting movable type in Asia involved ceramic, wood, and bronze. From the earliest days of printing in Europe through the end of the 19th century, alloys of lead were preferred. In the traditional method, each letter is cut actual size in reverse orientation on the end of a steel punch. Once the desired forms are achieved, each punch is hardened and driven into a block of brass to produce a matrix. This is fitted into a mold, and letters are cast directly from it in type metal. The alloy employed is, as a rule, 70% to 80% lead, 15% to 30% antimony, 5% to 10% tin, and 0% to 2% copper.

Linotype, Monotype and other patented hot-metal typesetting machines were extensively employed during the first two-thirds of the 20th century. The alloy used with these devices is generally higher in lead, free of copper, lower in tin and antimony, and therefore quicker to melt (and thus less durable) than foundry metal.

With the introduction of scalable digital type in the early 1980s, fonts rapidly returned to the form of disembodied information – just as immaterial, invisible, and weightless as they were in the days of the scribes but more profuse and more invariantly formed.

Type grows out of writing, and the world of the typographer grows directly out of the manuscript tradition. In the scribal cultures of Asia and Europe, librarians preserved not only texts but also the scripts in which they were written. Particular kinds of letterforms came to be associated with certain locations and languages, with certain kinds of literature, and then with certain scribal contexts and conventions. Roman capitals and uncials, for example, were retained for use in titles, initials, and headings long after they had ceased to be preferred for running text, and in multilingual manuscripts, different scripts were commonly employed for sacred and secular matter, or for Germanic and Romance languages, as they were for Latin and Greek. Professional scribes mastered not one hand or style of script but several, which they did not mix at random. In the scribal world, therefore, centuries before printing type was invented, letterforms had in effect been organized into fonts, stored in the hands and minds of experienced scribes and employed in accord with established conventions. 'Writing' was thereby formalized into 'typography' in a conceptual sense long before the first printing type was cut or printing machinery constructed. When movable type was initially adopted – in 11th-century China, 13th-century Korea, and 15th-century Europe – the aesthetic principles of typography were already well established. Only the technical problems remained to be solved.

The results were noticeably different when printing was introduced, often with missionary zeal, to oral cultures in Africa, the Americas, and Oceania. In the absence of any indigenous scribal tradition, typographical judgment is necessarily either arbitrary or alien and imposed. The Sequoyah syllabary used for Cherokee; the Evans syllabary used for Cree, Ojibwa, and Inuktitut; and the Pollard syllabary used for Western Hmong and some of its sister languages are examples of conscious creations which rapidly spread through their target communities. Each, however, was introduced into a scribal vacuum. Though each of these scripts remains in use and has been rendered typographically, an indigenous typographic aesthetic is still difficult to discern.

Wherever lasting scribal or typographic traditions have evolved, writing systems have been subject to the same social forces that affect the other arts and crafts. This means that scribal and typographic styles are prone to exhibit the same kinds of regional and historical variation found in architecture, literature, painting, and music. A taxonomy or history that fits these other arts is therefore apt to fit the corresponding typographic or manuscript tradition. Chinese script and print have changed, like Chinese architecture and painting, from the Sòng to the Míng and Qing dynasties and the postimperial era. European letterforms and page designs are easily identified as products of the Renaissance, Mannerist, Baroque, or Neoclassical period (Figure 3). Arabic, Greek, and Indic scripts likewise vary from age to age according to the Arabic, Greek, and Indic cultural calendars.

Figure 3 Renaissance, Baroque, Neoclassical and Romantic roman letterforms. Renaissance roman forms have a consistently *humanist axis*; Baroque forms have a *variable* axis which is still predominantly humanist; Neoclassical forms have a *rationalist axis*, and Romantic forms an exaggerated or dramatized rationalist axis. (Axis is defined as the orientation of the nib used to write the letters – or the nib that *would be used* to write them, if they were handwritten.) Renaissance, Baroque and Neoclassical letterforms all modulate gradually from thick to thin, while Romantic letterforms modulate more abruptly. (After Chappell & Bringhurst, 1999.)

Yet typefounding and printing have the power to separate scripts from their native places, just as they separate texts from their native times. Greek type was cut, and Greek books were printed, in Italy, France, Spain, England, and the Netherlands for 300 years before any printing was done in Greece itself. Arabic type was also cut and used in Western Europe long before it was made in the Middle East. The history of Greek and Arabic script and type has therefore been tied to the Western European cultural calendar for several centuries, while the history of Greek and Arabic literature, music, and architecture has not.

In Europe and its colonies, the Romantic age coincided with a rapid increase in the level of public literacy. Public consciousness of the historical mutability of letters also rose to an unprecedented level. In these conditions – when 'modern' was synonymous with 'romantic' – a simplified and popular historical taxonomy arose. Renaissance and Baroque letterforms came to be known as 'old-style'; neoclassical letterforms were called 'transitional'; and romantic letterforms were called 'modern.' Though it is thoroughly outdated, this crude and casual taxonomy remains in widespread use for the Latin alphabet.

A more basic taxonomic distinction – applicable to writing systems generally, not just to the Latin alphabet – is based on a single, simple test: do the glyphs have serifs or do they not? If yes, the type is serifed; if not, it is called unserifed or sanserif. (Professional typographers abbreviate these terms to 'serif' and 'sans.') From the perspective of European romantic taxonomy, sanserif type is 'postmodern,' – i.e., it is postromantic. In fact, however, the vast majority of writing systems are sanserif in their archaic incarnations. (This is true for Chinese, Greek, Latin, Hebrew, Arabic, and Korean script, among others.) Wherever artists are attracted to the archaic (as they were in Táng China, Renaissance Italy, and early modern Europe), sanserif letterforms are likely to be revived, at least for limited purposes. Only in the modern age, however, have sanserif forms become a typographic staple, widely used for printing text.

Ubriatova, Elizaveta Ivanovna (1907–1990)

O Molchanova, Uniwersystet Szczecinski, Szczecin, Poland

© 2006 Elsevier Ltd. All rights reserved.

Elizaveta Ivanovna Ubriatova (Ubriatova) was born in Irkutsk (the Russian Federation) in 1907 and died in Novosibirsk in 1990. She was a Russian turcologist whose linguistic work should be seen in the broad context of Siberian Turkic languages. Ubriatova's most substantial contributions to scholarship were her books and papers devoted to the dialectology, syntax, history, phonetics, and so on of the Yakut (Sakha) language as well as problems involved in the co-existence of Turkic with noncognate languages in the vast territories of Siberia.

Ubriatova was educated at the University of Irkutsk, and a year after her graduation from the university she was offered the position of a teacher at a primary school in Taimyr (the Taimyr national region), beyond the polar circle. In a short period of time, Ubriatova became acquainted with the Dolgan language and the life of its bearers and developed an interest in Siberian Turkic languages. To master them, Ubriatova took up postgraduate courses at the Institute of Peoples of the North in Leningrad (present St. Petersburg). Under the guidance of Academician Malov, she received an M.A. for her thesis entitled 'The language of the Norilsk Dolgan' in 1940 and a Ph.D. for her thesis 'Complex subordinate sentences in the Yakut (Sakha) language' in 1950. In Ubriatova (1950), younger scholars found both a thorough theoretical orientation and a manual of analytical procedures for all kinds of complex subordinate sentences.

In comparative linguistics she was a strong defender of three periods in the interaction of the Yakut language with a series of other languages: (1) the period of the Yakut language formation with all specific features of its grammatical structure: during a long period, some ancient people who spoke a language of Orkhon inscriptions lived side by side with groups of people who spoke Mongolian and Tungusic (Tungus); (2) the time when Mongolian and Tungusic groups switched to Turkic: at the end of this period, two dialects of Yakut (one retaining the unstressed *o* and another retaining the unstressed *a*) took shape; (3) the period of the Yakut language spreading beyond the boundaries of the territory between the Aldan and the Lena. Central to Ubriatova's thinking was the idea of similarity between Tofa (Karagas) and Tuvan (Tuvin), on the one hand, and Written Old Uyghur, on the other.

She was the first to point to Old Uyghur, from which attested grammatical features in the Turkic languages of South Siberia could be derived. The character of verb-forms occurring in Siberian Turkic languages made Ubriatova infer that there were three sources from which Turkic languages of Siberia had originated. The traces of Old Turkic languages – Orkhon-Turkic, Old Uyghur, and Kirghiz – occur in modern Turkic languages to a varied degree and may be assigned to different periods of time. The traces of later interaction overlap the earlier ones. One may assume that at first the Oghuz-Orkhon language was spread in the territory and a little later or simultaneously Old Uyghur began to extend its position and interact with the cognate Oghuz-Orkhon language.

As the character of verb-system in all modern Turkic languages in Siberia permits treating them as Kipchak, and as modern Kirghiz belongs to the same group, Ubriatova arrived at the conclusion that the source of Siberian Turkic languages' Kipchakization was Old Kirghiz.

Ubriatova received many honors, including the title of Honored Scientist of the Sakha Republic, Order of the Red Banner, two Badges of Honor and four medals. She has many disciples and followers where Turkic languages are studied and spoken.

Ueda, Kazutoshi (1867–1937)

M Miyawaki, Senshu University, Kanagawa, Japan

© 2006 Elsevier Ltd. All rights reserved.

Kazutoshi Ueda, founder of the modern scientific study of Japanese, was born in Tokyo on January 7, 1867. In 1885 he enrolled in the Department of Japanese and Chinese Literature, Faculty of Letters, Tokyo Imperial University. There he was initiated into the study of the Japanese language by Basil Hall Chamberlain and decided to devote his life to the subject. In 1890 Ueda was sent to Germany to study Indo-European linguistics. He studied first in Berlin and then in Leipzig under such leading linguists of the time as Georg von der Gabelentz and Karl Brugmann. On his return to Japan in 1894, Ueda was appointed professor of linguistics at Tokyo Imperial University, where he lectured on linguistics as he had absorbed it in Germany as well as on the history of Japanese indigenous efforts at linguistic studies (*kokugaku*). In 1899 he was awarded a D.Litt. In 1905 he was appointed to the chair of Japanese language, in which position he remained until his retirement in 1927. Outside the university, Ueda served as director of various bureaus of the Ministry of Education. He died in Tokyo on October 26, 1937.

Ueda's achievements can be divided into three areas: his own contributions to the scientific study of the Japanese language, his fostering of many disciples, and his activities for the cause of improving and standardizing Japanese. First, Ueda applied the methods of Indo-European linguistics to the study of Japanese. He demonstrated that modern Japanese *h* comes from *p* by way of *f* (e.g., *haha* 'mother' < *fafa* < *papa*), thereby laying the foundations of historical Japanese phonology. Second, Ueda produced many competent disciples. In the latter half of the 19th century, which marked the beginnings of modern Japan, his position as Professor of Japanese Language at Tokyo Imperial University meant that he was charged with the pioneering mission to foster young able scholars and to put them in the right places for the future development of the discipline. Among his pupils were Katsuji Fujioka (linguistics), Izuru Shinmura (philology), Kanji Matsui (lexicography), and Kyosuke Kindaichi (Ainu language). Third, Ueda engaged himself in various efforts outside the university to reform and standardize the Japanese language. He gave many lectures and published various articles for the purpose of improving the national language. He also helped the Ministry of Education to found the Committee for Investigating the Japanese Language. He himself became a member of the committee and contributed to the establishment of a standard Japanese and to the reform of the writing system.

Uganda: Language Situation

F Katamba, Lancaster University, Lancaster, UK

© 2006 Elsevier Ltd. All rights reserved.

Multilingualism is pervasive in Uganda. Ethnologue (2003) identifies 45 languages, including two extinct ones. No single language is dominant.

The Languages of Uganda

The indigenous languages show considerable genetic diversity. The Bantu subfamily of Niger-Congo has the largest number of languages and the most speakers. (Figures are vaguely indicative of the true picture. Numbers of speakers are from the 1991 census, and percentages are from Ladefoged *et al.*, 1971.) It includes Luganda (Ganda), with 3 015 980 and accounting for a little more than 16% of the population, plus an additional 1 million second language speakers. Another important language is Runyakitara (Nyankore, Runyoro, Rutooro, Rukiga and Runyankole), which represents about 25% of the country's population (cf. Ladefoged *et al.*, 1971; Byakutaga and Musinguzi, 2000).

Nilo-Saharan languages are spoken in the north and of the east of the country. The largest group is Western Nilotic, which includes Lango (977 680 speakers) and Acholi (746 796 speakers). There are also several Eastern Nilotic languages, the largest of which is Teso (999 537 speakers). Central Sudanic languages (e.g., Lugbara and Madi [Ma'di]) are spoken by about 6% of the population in the extreme northwest. The only Southern Nilotic language in Uganda is Kupsabiny, spoken by just 0.6% of the population.

Many small languages are endangered (e.g., Kuliak [Ik] and Rugungu [Gungu]); two are extinct namely, Lusinga (Singa) and Nyangi (Nyang'i).

The Indo-European languages English, Gujarati, and Hindi are also spoken in the country.

Language Policy

The 1995 Uganda Constitution allows the use of indigenous languages in any domain of public life. However, since no significant resources have been committed to modernizing them, this declaration remains a vain ambition. English, whose introduction was due to the colonization of the country, remains the official language. It is the language of today's elite: it is the language of political and social exclusion (e.g., parliamentary candidates must be proficient in English). But, for the rest of the population, it is also the language of aspiration, of modernization.

Voeglin and Voeglin (1977) estimated that there were 1 million speakers of English as a second language; the figure must be higher now. Most citizens have a rudimentary command of the language.

Current policy as outlined in the 1992 White Paper on Education is designed to entrench the status quo since it:

- recognizes English as the sole medium of education in urban primary schools
- restricts the use of vernacular languages as a medium of instruction to the first four years of school in rural districts and requires a switch to English from the fifth year
- makes English the only medium of instruction in all secondary schools.

The White Paper also makes both English and Kiswahili (Swahili) compulsory subjects in secondary schools. Despite this mandate, the position of English remains unassailable. In reality, the teaching of English is compulsory and enforced, whereas the teaching of Kiswahili remains optional, and take up is minimal. There have been some positive developments in recent years. Use of Ugandan languages in the media has increased with the explosive growth in the number of FM radio stations. Just as importantly, Uganda Sign Language (Ugandan Sign Language) was given a boost when it was officially recognized in the 1995 constitution.

Ugaritic

J A Hackett, Harvard University, Cambridge, MA, USA

© 2006 Elsevier Ltd. All rights reserved.

The Ugaritic language was rediscovered after a 3000-year gap, when, in spring of 1928, a farmer discovered a tomb at Minet el-Beida, on the Mediterranean, in what is now Syria, about 12 km from modern Latakia and a few hundred yards away from a large tell called Ras Shamra, 'Cape Fennel.' In 1929, the French began excavating what turned out to be a large necropolis. They soon moved on to the nearby tell of Ras Shamra, and in May of that year the first Ugaritic cuneiform clay tablets were found. After the first tablets were published in 1930, it was clear that the repertoire of signs was small (only 30), and so the writing system was assumed to be alphabetic and without vowels. Within months, the language was essentially deciphered. The identification of the site with ancient Ugarit was confirmed in the early 1930s with the discovery of a tablet that mentioned Niqmaddu, king of Ugarit.

Ugaritic is one branch of the Northwest Semitic languages, along with the Canaanite languages, the several forms of Aramaic, and other less well-documented languages. It is written in a cuneiform alphabet on clay tablets. Because the acrophonic linear alphabet predates the Ugaritic alphabet by several centuries, Ugaritic cuneiform was probably devised to adapt the idea of the alphabet to the medium of clay and stylus. Our earliest abecedaries, which are texts that list the letters of an alphabet written in a standard order, come from Ugarit, and they exhibit both the usual West Semitic order and, strikingly, the South Semitic order in a very few texts. Why abecedaries in this South Semitic order were present at Ugarit is so far unknown.

Ugaritic exhibits individual signs for 27 consonants of the West Semitic languages, plus three extra signs. There are two extra 'aleph signs, plus one for a sibilant that is used for loanwords. The three 'aleph signs are transcribed 'a, 'i, and 'u: 'a is used when an 'aleph in a word is followed by the vowel /a/, 'i is used when 'aleph is followed by /i/ or /e/ (<*ay), and 'u is used when 'aleph is followed by /u/ or /o/ (<*aw). A syllable-closing 'aleph is marked by 'i. These three signs have been very helpful in determining the vocalization of Ugaritic words, as have syllabaries that include Ugaritic words spelled out in Akkadian cuneiform, which is syllabic and so includes vowels. The Ugaritic consonants, given in the indigenous alphabet order, are ,' b, g, ḫ, d, h, w, z, ḥ, ṭ, y, k, š, l, m, ḏ, n, ẓ, s, ı, p, ṣ, q, r, ṯ, ġ, t (plus, as was noted above, two extra ' signs and a sibilant sign used for loanwords). The vowels reconstructed for Ugaritic are a, i, u, ā, ī, ū, o (<*aw), and e (<*ay). This cuneiform alphabet also exists in a shorter form of 22 signs, indicating that where this shorter alphabet is used, several mergers of consonants have taken place. A few tablets written in this shorter alphabet come from the site of Ugarit, but many were found farther south, at Sarepta and Kamid el-Loz in Lebanon, and at Taanach, Mt. Tabor, and Beth Shemesh in Israel.

The city-state of Ugarit was an important port, with its position on the Mediterranean and its proximity to Cyprus on the west, and its access to inland routes to the north and east. There are writings found at Ugarit in several different languages: besides Ugaritic, there are texts in Akkadian (the lingua franca of the time), Sumerian, Hittite (both syllabic cuneiform and hieroglyphic), Egyptian, Hurrian, and Cypro-Minoan. Texts found at the sites of Mari, Alalakh, and Amarna, among others, mention the city-state. The Ugaritic texts cover a short period of time, probably late 14th to early 12th century B.C. Excavation continues, but as of this writing, approximately 50 poetic texts and 1500 prose texts have been found at Ras Shamra and at neighboring Ras Ibn Hani. The poetic texts are mythological; the prose texts are ritual and other cultic texts, administrative documents, letters, omens, medical texts, and school exercises. The poetic mythological texts are characterized by parallelism, as in these couplets from the Baal myth:

> Sea sends messengers/Judge River, a delegation;
> Message of Sea, your master/your lord, Judge River.

Like other West Semitic languages, Ugaritic has prefix- and suffix-conjugation verbs, *yaqtulu/qatala*, but there are in addition two more prefix-conjugations: *yaqtul* and *yaqtula*. The prefix-conjugation *yaqtul* serves as both a jussive, or indirect imperative, and as a preterit. The prefix-conjugation *yaqtula* is less well understood, but appears to serve as a volitive form; it also, however, seems to occur in subordinate (especially purpose) clauses. The verb stems that are extant in Ugaritic are G, Gt, D, tD, N, Š (a causative), Št (reflexive of the causative).

Nominals in Ugaritic have masculine and feminine gender and singular, dual, and plural number. There are three cases in the singular – nominative, genitive, and accusative; the plural is diptotic – nominative and oblique. Nouns occur in both absolute (unbound) and bound states. The bound state is used for initial members of genitive chains called construct chains (*see* **Semitic Languages**) and for nouns before

pronominal possessive suffixes. There is no marked definite article in Ugaritic. There is evidence for -a- insertion in the plurals of nouns of the shape $C_1vC_2C_3$-: the (nominative) plural is $C_1vC_2aC_3$ūma. For example, 'king' (nominative) is *malku*, and 'kings' is *malakūma* (we can compare Biblical Hebrew *mélek*, plural *məlākîm*).

Ukraine: Language Situation

Editorial Team

© 2006 Elsevier Ltd. All rights reserved.

A major European power in the early middle ages, Ukraine had been part of the Polish–Lithuanian empire, of Czarist Russia, and after a short spell of independence, of the USSR until it became independent again in 1991. Ukraine is situated between Russia in the east and northeast; Belarus in the north; Poland, Slovakia, and Hungary in the west; and Romania and Moldova in the southwest. In the south, Ukraine has access to the Black Sea. The Crimean peninsula is an autonomous part of Ukraine.

Ukraine has a population of over 47 million people. The national and official language is Ukrainian, which is spoken by the majority (about 70%) of Ukrainians. Russian is the largest minority language, spoken by approximately 11 million first-language speakers, mainly in the industrialized east of the country and in urban centers, as well as by bilingual speakers. In addition to Ukrainian and Russian, Ukraine is home to a large number of languages, including communities of speakers of languages also spoken in neighboring countries, as well as small communities whose languages can be viewed as endangered. Among the larger communities are speakers of Polish (1 151 000), Belarusan (444 000), Romanian (250 000), Bulgarian (234 000), and Hungarian (187 000) in the west of the country. Languages of Ukraine that are not spoken as major languages in neighboring countries include Eastern Yiddish (634 000), Crimean Turkish (200 000), Jakati (156 000; spoken by the Jats, or 'gypsies,' of Afghanistan), Tatar (90 542), the Roma languages Carpathian and Vlax Romani, and Rusyn. The two Turkic languages, Urum, spoken in 10 villages in the Donetsk Oblast in southeastern Ukraine, and Karaim, spoken on the Crimean Peninsula, are endangered. The Crimean Peninsula was also the home of the last speakers of Gothic, which survived there until the 18th century.

A major European power in the early middle ages, Ukraine had been part of the Polish–Lithuanian empire, of Czarist Russia, and after a short spell of independence, of the USSR until it became independent again in 1991. Ukraine is situated between Russia in the east and northeast; Belarus in the north; Poland, Slovakia, and Hungary in the west; and Romania and Moldova in the southwest. In the south, Ukraine has access to the Black Sea. The Crimean peninsula is an autonomous part of Ukraine.

Ukraine has a population of over 47 million people. The national and official language is Ukrainian, which is spoken by the majority (about 70%) of Ukrainians. Russian is the largest minority language, spoken by approximately 11 million first-language speakers, mainly in the industrialized east of the country and in urban centers, as well as by bilingual speakers. In addition to Ukrainian and Russian, Ukraine is home to a large number of languages, including communities of speakers of languages also spoken in neighboring countries, as well as small communities whose languages can be viewed as endangered. Among the larger communities are speakers of Polish (1 151 000), Belarusan (444 000), Romanian (250 000), Bulgarian (234 000), and Hungarian (187 000) in the west of the country. Languages of Ukraine that are not spoken as major languages in neighboring countries include Eastern Yiddish (634 000), Crimean Turkish (200 000), Jakati (156 000; spoken by the Jats, or 'gypsies,' of Afghanistan), Tatar (90 542), the Roma languages Carpathian and Vlax Romani, and Rusyn. The two Turkic languages, Urum, spoken in 10 villages in the Donetsk Oblast in southeastern Ukraine, and Karaim, spoken on the Crimean Peninsula, are endangered. The Crimean Peninsula was also the home of the last speakers of Gothic, which survived there until the 18th century.

Ukrainian

S Young, University of Maryland Baltimore County, Baltimore, MD, USA

© 2006 Elsevier Ltd. All rights reserved.

Ukrainian, with some 36 million speakers in the Ukrainian Republic, forms with Russian and Belorussian the East Slavic branch of the Slavic language family. The standard language, which is written in the Cyrillic alphabet, has its roots in the 19th century – no enduring literary tradition had been able to form before this time – and is based on the relatively recent and uniform southeastern dialect. Since the late 19th century, the West Ukrainian (Galician) speech of L'viv has also played a role in the formation of the national standard.

Among the vocalic features that distinguish Ukrainian from the rest of East Slavic are the preservation of *o* in unstressed syllables: *vodá* /vodȧ/ 'water' (Rus., BR /vadȧ/), and the merger of East Slavic (ESl.) *i* with *y* to give a central-front mid vowel (represented in transliteration by *y*): *synij* 'blue,' like *syn* 'son' (Rus. *sinij* : *syn*). A new *i* developed in turn from ESl. *$\bar{e}$: *lis* /lʲis/ 'woods' (Rus., BR /lʲis/) and from *e* and *o* in a secondarily closed syllable: *šist'* 'six' (gen. *šestý*), *nis* 'nose' (gen. *nósa*). *e* > *o* after hushers and *j*: *čotýry* 'four,' *johó* 'his' (Rus. *četýre*, *jegó*), but *téplyj* 'warm' (Rus. *tëplyj* /tʲȯ-).

In contrast to Russian and Belorussian, Ukrainian consonants are not palatalized before *e* or *y* (the merger of ESl. *i* and *y*): *nestý* 'to carry' (Rus. *nestí* [-tʲi]), but there is palatalization before the new *i* representing ESl. *$\bar{e}$, *e*, *o*: *díty* [dʲi-] 'children' (Rus. *déti*), *nis* -nʲi-] 'nose' (Rus. *nos*). Stem-final *c* is typically palatalized: *kinec'* [-tsʲ] 'end,' gen. *kincjá* (Rus. *konéc, koncá*); final labials lose palatalization: *hólub* 'dove' (Rus. *gólub'*). Common Slavic /g/ has become /h/. Like Belorussian, Ukrainian has *w* (written *v*) corresponding to Russian *v* in a closed syllable: *právda* [prȧwda] 'truth,' and in some cases (including the masculine past tense marker) to *l*: *vovk* [vowk] 'wolf' (Rus. *volk*), *buv* [buw] 'was, masc.' (fem. *bulá*). Unlike other East Slavic languages, there is no regressive devoicing of voiced consonants: *kázka* 'tale' (with *z* preserved), or final devoicing: *did* 'grandfather' (with final *d*).

In addition to the six nominal case forms of Russian and Belorussian, Ukrainian has a regular vocative (*sýnu* 'son!,' nom. *syn*). As in Belorussian, there is an alternation of velar and dental stems in certain case forms: nom. *rik* 'year,' loc. *róci*; nom. *rih* 'corner,' loc. *rózi*. The verb has two regular conjugation patterns, illustrated by *nestý* 'to carry' (I) and *xodýty* 'to walk, go' (II): 1SG *nesú*, *xodžú*, 2SG *neséš*, *xódyš*, 3SG *nesé*, *xódyt'*, 1PL *nesemó*, *xódym*, 2PL *neseté*, *xódyte*, 3PL *nesút'*, *xódjat'* (like Belorussian, but unlike Russian, the 3rd person ending is palatalized). Unlike Russian or Belorussian, there is no alternation of velar and palatal stems in Ist conjugation verbs, the palatal stem having been generalized: *mohtý* 'to be able': *móžu*, *móžeš* (BR *mahú*, *móžaš*).

Lexically, Ukrainian lacks the Church Slavicisms characteristic of Russian (Ukr. *skoročú* 'shorten.1SG PF,' with ESl. *s-*, *oro*, *č*; cf. Rus. *sokraščú*, with ChSl. *so-*, *ra*, and *šč*), but shows a large number of borrowings from Polish: *cikávyj* 'interesting' (Pol. *ciekawy*, but Rus. *interésnyj*), *raxúnok* 'bill, account' (Pol. *rachunek*, but Rus. *sčët*), *otrymáty* 'to receive' (Pol. *otrzymać*, but Rus. *polučít'*).

Uldall, Hans-Jørgen (1907–1957)

R Thelwall, Calgary, Alberta, Canada

© 2006 Elsevier Ltd. All rights reserved.

Hans-Jørgen Uldall is most widely known for his *Outline of glossematics*, which was finally published only two months before his premature death. Born in Silkeborg, Denmark, the son of a doctor, he began studies at the University of Copenhagen in 1924 as a medical student, but soon changed to English and quickly drew the attention of his professor – Otto Jespersen. After studying under Daniel Jones in 1927, and achieving a native command of English, he was invited, in 1929, to teach at the University of Capetown as deputy for D. M. Beach. A teaching stint followed at the School of Oriental and African Studies (SOAS) for most of 1930. Then, on Jespersen's recommendation, in 1931 he went to California to carry out fieldwork for Franz Boas. He studied Southern Maidu in 1931 and in the summer of 1932. During his time in the United States, he studied anthropology under Boas at Columbia University and registered as an M.A. student there, although he never submitted his thesis. After some initial publication based on Jones's phoneme theory, he hesitated to complete his Maidu publication because he felt the need for a revised theoretical base.

In 1932, Uldall returned to Denmark and remained there until 1939. Jobs were hard to find, and Uldall had not completed his Danish degree. He had various temporary posts, initially associated with his old professor, Jespersen. He considered going abroad but his wife became ill with tuberculosis and died in 1937. Uldall was also kept in Denmark through his association with Hjelmslev, whom he had met shortly after returning, through the Linguistic Circle of Copenhagen. A phonology of Danish was planned under the Prague model but never completed. The work, involving Hjelmselv, Uldall, and Paul Lier, led to the development of a new theory that they called *glossematics* (q.v.). They planned various publications, but modifications to the theory delayed publication. In 1937 they agreed on the basic model and hoped to finish two publications on phonematics and Danish phonology. However, in 1939, Uldall felt obliged to take a post with the British Council in Athens, although he still intended to spend a significant part of the year in Denmark.

His intent was to go to Athens, but wartime circumstances prevented it. He found himself in Egypt instead, with his new bride, Elizabeth Anderson. They taught for the British Council in Cairo, Tel Aviv, Baghdad, and Alexandria. Throughout the war, Uldall was completely cut off from Hjelmslev. Their attempts to reestablish their working relationship of the late 1930s failed, interrupted by Uldall's further work for the British Council, and then for Tucuman University in Argentina, as well as work in Edinburgh (where Elizabeth, his wife, was appointed to the University in 1949). Even most of a year spent in Denmark (1931–1932) failed to further collaboration between the two, not least because their views had diverged. Hjelmslev felt unable to sign off on the proposed publication by Uldall, which was critical to his career. The publication appeared only two months before his death in Lagos, where he was a senior lecturer at the University of Ibadan.

Ulfilas (Ulfila, Wulfila, Urphilas) (ca. 311–382)

M K C MacMahon, University of Glasgow, Glasgow, UK

© 2006 Elsevier Ltd. All rights reserved.

Ulfilas was born ca. 311, probably in Gothia, north of the Danube but not part of the Roman empire, in what is now Rumania. His forebears were among a group of Roman prisoners abducted from Cappadocia (southern Turkey) by Goths in about 250. Nothing is known about his early life. Before the age of 30, however, he had acquired the position of *lector* (i.e., reader) in the Church. He was ordained Bishop to Gothia, probably in 341 in Constantinople – the evidence for the dating is debatable. The persecution of Christians some seven years later, in 347–348, forced him and others to flee southward from their home in Gothia to the comparative safety of the Roman province of Moesia. Thereafter his headquarters were located in what is now Bulgaria, about 200 km east–northeast of Sofia, in Turnovo.

Ulfilas espoused an Arian form of Christianity, believing that Christ was 'like' God, not 'of the same essence' as Him: the Homoean doctrine. Ulfilas and his fellow Christians in Moesia suffered no hardships from the Roman emperors because of their faith, until a few years before Ulfilas' death when the emperor Theodosius I (347–395) instituted political and property changes among the Arians, which saw Arianism decline in favor of Catholicism. Ulfilas was summoned to meet Theodosius in Constantinople – the exact reasons for which are unclear. He subsequently died there, in either 382 or 383.

The sources for his life are comparatively limited, and are to be found in the works of eight early medieval historians from the 5th to the 9th centuries. Of these, the two most informative are by Auxentius of Durostorum (i.e., Silistra, about 100 km southeast of Bucharest), and Philostorgius. Auxentius (fl. ca. 400) was a pupil, and also the foster son, of Ulfilas, and his *Epistola de fide, vita, et obitu Ulfilae* describes in some detail the main features of Ulfilas' life, especially his religious opinions. It makes no mention, however, of his translation of the Bible into Gothic. Philostorgius (368–ca. 433) stated that Ulfilas "was the inventor for [the Goths] of their own letters, and translated all the Scriptures into their language – with the exception ... of [the Books of] Kings. This was because the books contain the history of wars, while the Gothic people, being lovers of war, were in need of something to restrain their passion for fighting rather than to incite them to it" (Heather and Matthews, 1991: 144). The 6th-century Gothic historian Jordanes noted that Ulfilas "is said also to have taught them how to write" (idem); Isidor of Seville (ca. 570–636) merely repeated the assertion that Ulfilas invented the Gothic alphabet and translated the Old and New Testaments, as did Wala(h)frid Strabo (c. 809–849) more than two centuries later (Streitberg, 1908: xxiv–xxv). The comments on Ulfilas by Socrates Scholasticus (5th century), Sozomen (5th century), and Theodoret (ca. 393–ca. 458) add nothing further to our understanding of his role as translator. Ulfilas is reputed to have been a fine preacher; he also wrote a series of tracts and commentaries/translations on Arian matters in Greek, Latin, and Gothic, none of which have survived.

Ulfilas is important in the history of the development of Christianity in southeastern Europe, especially in the formulation of Christian doctrines and the maintenance of Arianism. From a specifically linguistic viewpoint, his translation of the Bible, parts of which have been preserved (*see* **Gothic**), provided scholars of the early Germanic languages with a major source of crucially significant textual materials.

Ullendorff, Edward (b. 1920)

D Appleyard, University of London, London, UK

© 2006 Elsevier Ltd. All rights reserved.

Edward Ullendorff (b. Zürich 1920) is one of the leading British figures in Ethiopian studies during the second half of the 20th century. After studying at the Hebrew University, Jerusalem, in the-then Palestine, and following various positions with the British Administration, first in Eritrea and Ethiopia between 1942 and 1946, and briefly in the Palestine Mandatary Government between 1947 and 1948, Ullendorff began his academic career in Oxford, where he tutored Colonial Service cadets in Arabic. Then, in 1950, he was appointed Lecturer in Semitic Languages at the University of St Andrews. His experience in Eritrea and Ethiopia allowed him to develop what was to become his main field of study throughout his academic career, the Semitic languages of Ethiopia. Much of Ullendorff's published work in this field focuses more on what may be called the philological rather than the linguistic, the first of his major books being *The Semitic languages of Ethiopia: a comparative phonology* (1955), which is the published version of his doctoral dissertation. During the years before 1959, when he moved to the University of Manchester to take up the Chair in Semitic Languages and Literatures, he also wrote and reviewed on other areas of Semitic studies, ranging from Hebrew and Aramaic to South Arabian, as well as the field of Ethiopian studies. Reviewing academic books has always been one of the most active areas of Ullendorff's writing; indeed, his bibliography reveals over 300 reviews in more than 60 years of publications. In Manchester, he continued to work equally on Ethiopian matters as well as on wider Semitic themes, especially Biblical and Ugaritic studies, to which he has returned on various occasions throughout his career. It is also indicative of his wide-ranging scholarship that he has never confined himself to 'languages and literatures' in the strictest sense. Thus, in 1960, there appeared the first edition of his book *The Ethiopians: an introduction to country and people,* a highly readable and informative book that has seen several reprints and four editions, the latest published in 1998 in Kingston, Jamaica. Possibly his most outstanding book-length publication, *Ethiopia and the Bible – the Schweich lectures of the British Academy* (1968), is eloquent testimony to the philology-based range of his scholarship, covering as it does a broad canvas of textual sources in Semitic languages.

In 1964, Ullendorff moved to the School of Oriental and African Studies to take up the Chair in Ethiopian Studies that had been specially created for him. This was the first Chair in Ethiopian Studies anywhere in the world. Ullendorff remained as Professor of Ethiopian Studies until 1979, when he exchanged that position for the Chair in Semitic Languages. On his retirement in 1982, the University of London conferred upon him Emeritus status in terms of 'Semitic Languages and Ethiopian Studies,' thus giving recognition to both of the chairs that he had held. During his time in London, the study and teaching of Ethiopian languages was begun on a regular basis, greatly aided by his *An Amharic chrestomathy* (1965), which was followed some years later by a similar volume, *A Tigrinya* (*Təgrəňňa*) chrestomathy (1985). Also notable is his translation from Amharic of the first volume of Emperor Haile Sellassie I's autobiography (1976).

In 1988 he published an account of his early adult years, *The two Zions: reminiscences of Jerusalem and Ethiopia*, and in 1989 he was honored with a dedicated volume of the *Journal of Semitic Studies*, which contains a comprehensive bibliography of his writings up to that point (Hopkins, 1989).

Ullmann, Stephen (1914–1976)

F Kerleroux, Université de Paris X, Paris, France

© 2006 Elsevier Ltd. All rights reserved.

Stephen Ullmann was born in 1914 in Budapest, where he attended university, obtaining a doctorate in 1936. In England, during World War II, he worked for the BBC and never returned to Hungary. His first university appointment was to the University of Glasgow, from 1946–1953, then to the chair of Roman philology at Leeds, and finally chair of Roman languages at Oxford, until his death in 1976. He was a director of the philological journal *Archivum Linguisticum* (1949–1962) and president of the Philological Society (1970–1974).

In the two fields of semantics and of stylistics, which he did not define as separate areas of linguistics, Ullmann played an important role by introducing to English-speaking universities the research of the French, such as Alfred Darmesteter's *La vie des mots étudiés dans leur signification* (1887), Michel Bréal's *Essai de sémantique* (1897), and especially Ferdinand de Saussure's contributions (*Cours de linguistique générale*, 1916), characterizing the distinction between diachrony and synchrony as a "Copernican revolution" – Ullmann also introduced the main studies of German and other European scholars who had influenced him during his formative years (e.g., Jost Trier, *Der deutsche Wortschatz im Sinnbezirk des Verstandes*, 1931; Gombocz and Weisberger, *Muttersprache und Geistesbildung*, 1929). As well, his Germanic studies in philology and in philosophy were extensive (*see* **Bühler, Karl (1879–1963); Husserl, Edmund (1859–1938)**).

The principles of semantics: a linguistic approach to meaning, an erudite synthesis packed with notes and references, was, when published in 1951, welcomed by the main researchers in the field, such as John Lyons and Pierre Guiraud. Here, for the first time, the common denominator of different problematics is studied and is revealed as organizing conjointly the areas of descriptive, historical, and general semantics.

His *Précis de sémantique française* (1952), although more ambitious, was less convincing. Its aim was to delineate the dominant semantic traits of a specific language, but the book seems to contain a number of common opinions about the French vocabulary, such as: the French word is essentially abstract, it is altogether polysemous and comprises many homonyms, Latinate words constitute a state within a state, and the French word's semantic autonomy is relatively weak – more than the word in other languages, the French word needs to be within a context to be understood.

Unaccusativity

A Zaenen, Palo Alto Research Center, Palo Alto, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

The core observation leading to the unaccusative hypothesis is that intransitive verbs exhibit two different syntactic patterns and that in one of them, the subject has important characteristics in common with the object of a transitive verb. The verbs whose subjects have object-like behavior are called unaccusative, and the other intransitive verbs are unergative. (During the 1980s there was an attempt within government binding theory to call unaccusatives ergatives.) The coinage, attributed to Geoff Pullum, is introduced in David Perlmutter's seminal paper (1978) 'Impersonal passives and the unaccusative hypothesis.' That paper can be considered the starting point of much research over the past 25 years, but there is earlier work drawing attention to object-like properties of intransitive subjects. Perlmutter (1978) himself mentioned Sapir (1917). Hall (1965) and Chvany (1975) pointed out that some clauses seem to lack deep subjects in English and Russian, respectively, and Napoli (1973) hypothesized underlying objects that advance to subjects for Italian verbs. Other early sources are documented in Pullum (1988).

The unaccusative hypothesis has led to three major areas of investigation:

- the determination of (language-specific) diagnostics distinguishing unaccusative from unergative verbs
- the semantic correlates to the syntactic distinction
- the theory-specific formulations of the hypothesis and attempts to explain it.

In what follows I will use terms like 'underlying' or 'deep' objects to refer to the subjects of unaccusative verbs. This doesn't express a commitment to the idea that the only possible analysis of such a subject requires the postulation of an underlying object. In a later section, I observe that some frameworks accommodate the unaccusative hypothesis without such an assumption.

Diagnostics for Unaccusativity

Unaccusativity has been studied in a great variety of languages, and many different diagnostics have been proposed. I will limit myself to those that are syntactic in nature and apply in simple clauses. I will also ignore the attempts to extend unaccusative analyses to adjectives, and I will concentrate on the diagnostics for Germanic, Romance, and Slavic languages, assuming they are the most accessible. But the interested reader can find comparable discussions of, for example, Acehnese (Aceh), Basque, Choctaw, Georgian, Greek, Hebrew, Japanese, Lithuanian, Sanskrit, Saramaccan, and Turkish.

Impersonal Passive

The phenomenon that Perlmutter (1978) discussed in detail is the impersonal passive.

The construction is illustrated for Dutch in (1)

(1) er wordt hier door de jonge lui veel gedanst
it is here by the young people a-lot danced
'the young people dance a lot here' (Perlmutter, 1978: 168)

This corresponds to the active in (2).

(2) de jonge lui dansen hier veel
'the young people dance here a-lot'

It is possible with some verbs, claimed to be unergative verbs, and not with others, claimed to be unaccusative. An ungrammatical example is given in (3).

(3) er werd door vele kinderen in de rook gestikt
it was by the children in the smoke suffocated
'many children suffocated in the smoke' (Perlmutter, 1978: 170)

Example (3) corresponds to the active in (4).

(4) vele kinderen zijn in de rook gestikt
many children are in the smoke suffocated
'many children are suffocated in the smoke' (Perlmutter, 1978: 170)

It is the unaccusative phenomenon of choice in the theoretical context of relational grammar that frames Perlmutter's discussion because two of the claims of relational grammar are that there is only one promotion from object to subject per clause and that passive cannot involve spontaneous demotion. Impersonal passive is not possible with unaccusatives because, by the unaccusative hypothesis, their active subject is the result of an advancement from object to subject, and only one such advancement is possible. Impersonal passive has been discussed as an unaccusative diagnostic in, *inter alia*, Dutch (e.g., Perlmutter, 1978; Hoekstra, 1984; Zaenen, 1988, 1993), German (German, Standard) (e.g., Shannon, 1987; Grewendorf, 1989), and Turkish (e.g., Perlmutter, 1978). Not all these discussions agree on the relevance of the diagnostic (see discussion below).

Note that the references given here and in the rest of this article pertain only to discussions of the phenomena that refer to unaccusativity. They are meant only to point the interested reader in the right direction.

Auxiliary Selection

Early work on unaccusativity, with the contributions of Rosen (1981) and Burzio (1981), focused on Italian. One of the diagnostics they discussed is auxiliary selection (first examined in Perlmutter, 1989, the published version of a paper drafted more than ten years earlier). The contrast can be illustrated by (5) and (6) (from Rosen, 1984: 44):

(5) Mario ha esagerato
Mario has exaggerated
Mario exaggerated

(6) la pressione è aumentata
the pressure is increased
'the pressure increased'

The diagnostic is deemed to be relevant because in Italian the auxiliary for the passive voice is also *essere* (to be). So again a generalization can be made: *essere* signals that an advancement from object to subject has taken place. The diagnostic has been discussed for several Germanic and Romance languages. We cite, *inter alia*, Dutch (Hoekstra, 1984; Everaert, 1986; Zaenen, 1988, 1993), French (Legendre, 1989), German (Grewendorf, 1989), and Italian (also Rosen, 1984; Burzio, 1986; Van Valin, 1990; Sorace, 2004; Legendre and Sorace, 2004).

Ne-Cliticization

Another Italian diagnostic that has been discussed extensively in the literature is *ne*-cliticization, exemplified in the contrast between (7) and (8) (from Bentley, 2004).

(7) ne arrivano molti
NE *arrive*-PL *many*-PL
'many of them arrived'

(8) *ne studiano molti.
NE *study*-PL *many*-PL
'many of them study'

The situation is a bit more complex than with the two previous diagnostics because sentences such as (7) are grammatical only when the subject follows the verb. The version in (9) is not acceptable (Burzio, 1986: 21):

(9) *molti ne arrivanono
many NE *arrive*-FUT-PL
'many of them will arrive'

Only a postverbal subject can float *ne*-clitics. And, as we would of course expect, so can objects, as illustrated in (10) (from Rosen, 1984: 49).

(10) ne ho visti tre
NE *have-1*SG *seen three*
'I saw three of them'

Levin and Rappaport Hovav (1995) saw *ne*-cliticization as a manifestation of surface unaccusativity because the argument of the intransitive verb actually occurs in object position and there is no direct appeal to the underlying status of the argument, as there is with auxiliary selection and passivization.

Ne-cliticization as such is obviously restricted to Italian. Some attempts have been made to extend the analysis to clitic phenomena in other languages, mainly in Romance. Relevant studies for Italian are Rosen (1981), Burzio (1981, 1986), Belletti (1988), Van Valin (1990), and Bentley (2004).

Participial Constructions

Some intransitive verbs can appear in the participial absolute construction in Italian, and others cannot, as illustrated in the following examples (adapted from Rosen, 1984).

(11) arrivati i Frabiani scoppiarono gli applausi
arrived the Frabians exploded the applause
'after the Frabians arrived, the applause exploded'

(12) *resistiti i Frabiani scoppiarono gli applausi
stood-firm the Frabians exploded the applause
'after the Frabians stood firm, the applause exploded'

Again, verbs such as *arrivare* (to arrive) pattern with objects here.

This diagnostic has been discussed for other Romance languages; for French, see Legendre (1989) and Legendre and Sorace (2004). It is one of the participial distinctions that are conditioned by the unergative/unaccusative distinction.

Another is the adjectival perfect participle in Germanic, illustrated by the following contrast:

(13) the fallen leaf

(14) *the laughed boy

Again (13) exhibits the same behavior as subjects of passivized transitive verbs (*the painted house*). This diagnostic was proposed for Dutch by Hoekstra (1984). Across languages, it seems to be one of the diagnostics that is deemed the most reliable.

Resultatives

A more subtle manifestation of unaccusativity can be seen in the following contrasts (from Levin and Rappaport Hovav, 1995: 39, 35, 63).

(15) the river froze solid

(16) *Dora shouted hoarse

(17) Dora shouted herself hoarse

(18) Terry wiped the table clean

This construction is considered to be the diagnostic par excellence for unaccusativity in English by Levin and Rappaport Hovav (1995), who discussed it extensively. I refer to them for references about the resultative construction in general. With respect to unaccusativity, the fact to notice is that a resultative can be predicated of an object, as in (18), and of subjects that under the unaccusative hypothesis would be considered to be underlying objects, as in (15), but not of subjects like (16) except when a reflexive is added, as in (17).

Genitive of Negation

Subjects of unaccusatives in Russian can receive genitive case under negation, as do objects, and in contradistinction to the subjects of unergatives, as illustrated in the following contrasts.

(19) otveta ne prišlo
answer-GEN NEG came
'no answer came' (Originally from Babby, 1980; cited in Harves, 2002: 34)

(20) Anna ne kupila knig
Anna NEG bought books-GEN
'Anna didn't buy books' (Harves, 2002: 34)

(21) *ni odnoj devuški ne pelo
not single girl-GEN NEG sang
'not a single girl sang' (Harves, 2002: 34)

This contrast was first mentioned in the context of unaccusativity in Pesetsky (1982). For a recent discussion, see Harves (2002). Note that the verbs in this construction do not agree with the genitive; they are in an impersonal form, and not all analyses assume that all genitive arguments of intransitives are to be analyzed as surface subjects.

Po-Phrases in Russian

Po-phrases in Russian are used to indicate distributivity. They are felicitous with unaccusative subjects and with objects but not with unergative subjects, as illustrated below.

(22) ja dal mal'čikam po jabloku
I gave boys-DAT PO apple-DAT
'I gave the boys an apple each'

(23) po jabloku upalo s každogo dereva
PO apple-DAT fell from each tree
'an apple fell from each tree'

(24) *v každoj kvartire smejalos' po mal'ciku
in each apartment laughed PO boy-DAT
'a boy laughed in each apartment' (examples cited in Harves, 2002: 35)

This was also first observed in Pesetsky (1982). Again the verbs in this construction are impersonal (they don't agree with the hypothesized subject). Recent discussions can be found in Harves (2002) and Schoorlemmer (1995). A similar potential diagnostic is discussed for Spanish in Bosque (1992).

Na-/Pere-/Po-Prefixation in Russian

According to Schoorlemmer (1995) and others, prefixation with *na* ('to V a lot') or *pere/po* ('to V all') leads to quantification of the object with transitive verbs and of the subject with unaccusative intransitives. It is ungrammatical with unergatives.

(25) diti *na*kupili *mnogo* knig
children bought many books-GEN
'the children bought a lot of books'

(26) *mnogo* travy *na*roslo v parke
much grass-GEN grew in park
'a lot of grass grew in the park'

(27) **mnogo* detej *na*igralo v parke
many children-GEN played in park
'many children played in the park' (examples cited in Harves, 2002: 104–105)

Positional Phenomena

A number of diagnostics have been proposed in which the underlying object shows up in object position on the surface and the subject position is filled either with another argument or a dummy (such as *there*) or left unfilled. Depending on the analysis, the underlying object can be claimed to be the surface object, and a dummy, overt or not, or another constituent can be postulated to be the subject, or when the theory allows it, the construction can be treated as subjectless.

Inversion in Romance

In Italian, inversion constructions are the ones that allow *ne*-cliticization (see above). Their postverbal argument is analyzed as a subject in object position (Belletti, 1988; Rosen, 1981).

Unaccusative Inversion

Marandin (1999) singled out one type of French inversion construction as being an unaccusative construction because the postverbal element has several

object-like properties. The construction is illustrated in (28). It should be distinguished from the better-studied stylistic inversion, in which the argument does not have these object-like properties.

(28) je voudrais qu'en vienne au moins un autre
I would like that EN *come at least one other*
'I would like at least one other one to come'
(Marandin, 1999: 7)

Among the objectlike properties of the postverbal argument are *en*-clitics, nonoccurrence with an(other) object, and the restriction of the construction to non-agentive verbs. The author assumes that the postverbal argument is a surface object. See also Legendre and Sorace (2004) for discussion.

Locative Inversion

The construction is exemplified in English in sentences such as

(29) In the distance appeared the towers and spires of a town which greatly resembled Oxford (from Bromfield, L., *The farm*, cited in Levin and Rappaport Hovav, 1995).

It is discussed *inter alia* in Levin (1987), Bresnan (1984), and Levin and Rappaport Havav (1995). Again, the postverbal argument can be analyzed as a surface subject or a surface object. Similar constructions have been discussed as unaccusative in Spanish and Russian, for example.

Inversion with Psych-Verbs

In several languages we find a class of psychological and related predicates with two nominal arguments, one of which is clearly nominative and one which is, as far as one can tell, not accusative. The word order with these verbs tends to be more flexible than with other two-argument verbs. For instance, in Dutch we find the following possibilities.

(30) ...dat de teugels *hem* zijn ontglipt
...that the bridles him are slipped
'...that the bridles have slipped from his hands'

(31) ... dat *hem* de teugels ontglipt zijn (Everaert, 1986: 114)

This second word order is not possible with other predicates, as illustrated in (32–33)

(32) ??...dat *ons* de kinderen hebben geërgerd
...that us the children have annoyed
'...that the children have annoyed us'

(33) ...dat de kinderen *ons* hebben geërgerd.

These word order facts are discussed in, for example, Everaert (1986) as possible diagnostics for unaccusativity. For Italian experiencer verbs and their relevance to unaccusativity, see Perlmutter (1983) and many others.

First Conjunct Agreement in Inversion in Russian

When a conjoint nominative subject is in postverbal position in Russian, the verb can show singular agreement with the first conjoint. It has been claimed (Harvis, 2002) that this is possible only with unaccusative verbs.

(34) k beregu bežal Kolja I Vanja
*towards shore ran-*MASC-SG *Kolya and Vanya*
'Kolya and Vanya ran to the shore' (cited in Harvis, 2002: 37)

(35) *na večěre igral Andrej I Kolja
*at the party played-*MASC-SG *Andrej and Kolya*
'Andrej and Kolya played at the party' (cited in Harvis, 2002: 38)

Extraction Phenomena

The potential influence of the unaccusative-unergative distinction on *wh*-type constructions has not been discussed extensively except in Grewendorf (1989), who drew attention to several types of extraction asymmetries that seem to be influenced by the distinction in German. I illustrate two of them: *was-für* split and partial VP fronting.

Was-Für Split

While the example in (36) is ungrammatical, the sentence in (37) is acceptable.

(36) *was haben für Leute gearbeitet?
what have for people worked
'what kind of people have worked?'

(37) was sind für Leute angekommen?
what are for people arrived
'what kind of people have arrived?'
(Grewendorf, 1989: 30)

It was already observed for the Dutch equivalent of the construction (see, e.g., Everaert, 1986) that this kind of split (*wat voor* in Dutch) is in general acceptable with direct objects and unaccusatives. Grewendorf (1989) extended the analysis to German but noted that there is speaker variation and that the grammaticality of the result depends on the position of the nominative argument: only when it is in 'object position' is the split extraction allowed, as illustrated with the following contrast.

(38) was sind dem Lehrer für Fehler aufgefallen?
what are the teacher-DAT for mistakes been-striking
*was sind für Fehler dem Lehrer aufgefallen?
what are for mistakes the teacher-DAT been-striking
'what kind of mistake has the teacher noticed?'

Was-für split is thus a positional phenomenon like *ne*-cliticization in Italian.

Partial VP-Fronting

The term 'partial VP-fronting' refers to the fronting of a participle or an infinitive with some of its non-subject arguments. In some cases, however, German also allows the fronting of a nominative argument together with the participle, as illustrated in (39).

(39) eine Concorde gelandet is gestern in München-Riem
a Concorde landed is yesterday in Munich-Riem
'a Concorde landed yesterday in Munich-Riem'
(Grewendorff, 1989)

This has been claimed to be limited to unaccusative verbs and indefinite arguments, but the conditions on this construction are far from clear.

Other extraction phenomena discussed by Grewendorf (1989) are extractions out of NP subjects and out of subject sentences, and discontinuous phrases of the following kind:

(40) weine haben dem Hans auch billige geschmeckt
wines-NOM have the John-DAT also cheap tasted
'John enjoyed also cheap wines'

The Status of Reflexive Constructions

For languages in which it can be argued that reflexivization is a kind of intransitivization and that the reflexive is not an argument but a morphological marker, it has often also been argued that reflexive clauses are unaccusative clauses (see, e.g., Marantz, 1984). This type of analysis remains very controversial.

As said above I will not discuss morphological or biclausal diagnostics. The most prevalent of the morphological ones is *-er* suffixation, which has been studied for English in Levin and Rappaport Hovav (1995) and earlier work and for Dutch in Hoekstra (1984).

Complex clause arguments are mainly discussed for French in Legendre (1989), who gives the behavior of embedded infinitives under *croire* and *laisser* as diagnostics as well as object raising ('easy to please' constructions). The behavior of infinitives under *lassen* has also been discussed for German (Grewendorf, 1989).

Language-Internal Mismatches

The previous sections show that there is a wealth of evidence for the conclusion that not all intransitive verbs are created equal. For all these differences to be reflexes of nothing but the unaccusative–unergative distinction, however, it should be the case that, if there are several tests within one language, they pick out the same verbs, or at least the same verb meanings. From the beginning on, there have been doubts about this. Levin (1987) discussed mismatches with respect to unaccusative tests in Dutch and English. Similar observations have been made for German (Kathol, 1991) and for Italian (Bentley, 2004). These mismatches point to the need for other factors to be taken into account, to supplement or replace the unaccusative hypothesis. This has led to investigations of the semantic factors that underlie the unaccusative–unergative distinction.

Semantic Correlates

Perlmutter (1978) already observed that the syntactic distinction opposing unergative and unaccusative intransitives correlated with semantic distinctions. The unergatives that his impersonal passive test picks out tend to describe volitional acts and some involuntary bodily processes whereas the unaccusatives are verbs with a semantic patient as argument, as well as verbs of existing and happening, nonvoluntary emission of stimuli, aspectual predicates, and duratives.

The existence of these correlates has led to attempts to reduce the distinction to a matter of semantic classes. For instance for Dutch, Zaenen (1988) argued that there are two semantic distinctions at work, (a) the aspectual opposition between telic and atelic predicates, which conditions auxiliary selection and past participle behavior, and (b) the volitional one, which conditions the possibility of forming impersonal passives. For Italian, Van Valin (1990) claimed that auxiliary selection depends on the presence of a state predicate in a Dowty decomposition of the meaning of predicates. Rosen (1984) argued against the attempts to reduce the unaccusative–unergative distinction to semantics both across languages (the 'universal alignment hypothesis' of Perlmutter and Postal) and language internally (her 'little alignment hypothesis'). The universal alignment hypothesis states that there are principles of universal grammar that predict the initial relations borne by each argument on the basis of the meaning of the predicates. Rosen argued against it by pointing out apparent counterexamples, but for several of her examples it is not clear that verbs that she considered to have the same meaning

are indeed completely synonymous. Verbs that are translations of each other can in fact belong to different aspectual classes. The little alignment hypothesis assumes only consistency of the mapping between meaning and initial grammatical function within each language. Here again, it is not clear that Rosen kept the meaning constant in her contrasts. In fact, in certain cases she compared transitives and intransitives that have a different mapping from argument structure to grammatical function, as illustrated in the following example:

(41) Bertini ha calato il sipario
'Bertini has lowered the curtain'

(42) il sipario è calato
the curtain is fallen
'the curtain fell'

It is clear that the relation between the two subcategorization frames and the semantic roles associated with the arguments in this example lends itself very easily to an analysis that preserves the little alignment hypothesis. In general Rosen's observations do not warrant her conclusions. As discussed in Grimshaw (1987), the relation between the various diagnostics and the distinction itself might not be completely straightforward.

Initial attempts to isolate semantic correlates for unaccusativity, however, have also come under attack. For Dutch, for instance, Hoekstra (1999) claimed there is no satisfying semantic criterion.

The most sophisticated attempt to date to reconcile the observations about semantic correlates, mismatches, and the object-like behavior of some intransitive subjects that is the basis of the unaccusativity hypothesis is that of Levin and Rappaport Hovav (1995), who eliminated what they call surface unaccusativity, mainly positional phenomena, from the picture and proposed four partially ordered mapping rules to account for the semantic classes that correlate with the unaccusative–unergative distinction. They hypothesized that

- arguments undergoing directed change map onto underlying objects, as well as
- arguments whose existence is asserted or denied, whereas
- arguments that denote immediate causes map unto underlying subjects. Finally
- a default rule maps other arguments to objects.

The problem with their account is that notions such as 'directed change' and 'immediate cause' are not given an operational definition apart from unaccusativity, which makes the proposal rather circular.

The observation that unaccusative verbs in different languages tend to be similar but different has led to another type of theorizing, represented by the work of Sorace and Legendre. Sorace (e.g., in Sorace, 2004) proposed gradient hierarchies based on aspectual parameters, predicting that the closer a verb is to expressing a 'telic dynamic' change, the more likely it is to be unaccusative, whereas when it expresses an 'atelic nondynamic activity,' it will be unergative. Different languages and different constructions have different cutoff points on this hierarchy for verbs that exhibit syntactic unaccusativity. This is further formalized in optimality theory in Legendre and Sorace (2004). This proposal too has the problem of appealing to ill-defined semantic notions.

Theory-Specific Formulations of the Hypothesis

While there has been much discussion about what motivates the unaccusative–unergative distinction, it has not been difficult for any syntactic framework to accommodate it if so desired.

In multistratal theories such as relational grammar and government binding theory, the unaccusative subject is treated as an underlying object. In relational grammar this means that it is a two in the initial stratum and a one in a later one, the final one (if no dummy insertion has occurred and the predicate is not in a raising construction). In government binding theory, the unaccusative subject is hypothesized to have originated within the VP, it is an internal argument just like any other object, and it is moved to the external argument position (the subject position) (Burzio, 1981, 1986). In both these theories, we need a principle to make sure that this movement happens. In both cases it is a requirement that all clauses have a subject, supplemented in government binding theory by Burzio's generalization that verbs lacking an external argument can't assign accusative case. In late government binding theory approaches and in the minimalist framework, all arguments tend to originate in a VP internal position; hence unergatives and unaccusatives need to be distinguished in a different way. Given the number of different projections available, this has not proven to be a problem (see, e.g., Alexiadou *et al.*, 2004: 14 for a proposal). In these recent approaches, several projections are available, and different semantic phenomena can be linked to those, allowing for the representation of more fine-grained distinctions than just the unaccusative–unergative opposition.

In monostratal theories, the unaccusative–unergative distinction is represented as a difference

on the level of argument structure. In lexical functional grammar, the analysis was first proposed in Levin (1987). It is further developed in Bresnan and Zaenen (1990) and Zaenen (1993). The main idea is that an unaccusative argument is classified as −r (nonrestrictive), the same way as canonical objects. This allows it to be realized as a subject or an object, and assuming a principle that will force it to become a subject when there is no other subject candidate, it will surface as such in passives and unaccusatives. In head-driven phrase structure grammar, the original proposal (Kathol, 1991) was simply to add an attribute ERG to the lexical entries of unaccusative subjects and canonical objects. This attribute would be deployed in lexical roles and either allow or block their application; for example, in the passive rule, it would regulate what could become the subject of a passive. In later versions of the theory, the head-driven-phrase-structure-grammar version of argument structure and roles assignment is exploited. For instance, Blevins (2003) proposed a stem representation in which unergative arguments have a SUBJ and an argument structure (ARG-S) attribute with the same value, whereas unaccusatives only have an ARG-S attribute. On the word level, the representation for both contains a SUBJ attribute, and a lexical mapping constraint ensures that the highest value of the ARG-S is also that of the SUBJ.

Other theories deny the relevance of the unaccusative–unergative distinction and try to develop purely semantic approaches to the so-called unaccusative phenomena. This is, for instance, the direction chosen in role and reference grammar (Van Valin, 1990). However, as Levin and Rappaport Hovav pointed out, to explain fake reflexives in resultatives, Van Valin would have had to appeal to some syntactic generalization (Levin and Rappaport Hovav, 1995: 71).

Of course, representing the unaccuative–unergative distinction is not explaining it. Most attempts at explanation tend to be more or less disguised stipulations, and a discussion of them would require more detail about the various linguistic theories than is possible here. I refer interested readers to the literature in the theory of their choice. Whether an ultimately satisfactory explanation will maintain a unified unaccusative–unergative opposition or split up all the phenomena that have been studied as part of the opposition and explain them in different ways, only the future can tell.

Underspecification

S Inkelas, University of California, Berkeley, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

Underspecification in phonology is the partial description of lexical entries, intermediate forms (phonological underspecification) or surface forms (phonetic underspecification). Motivations for underspecification range from language-particular descriptive necessity to the desire to capture universal phonological generalizations.

Underspecification is a relative notion, defined by the absence of specification in any given form for features or metrical structures that play an active role in the language. Phonological underspecification is the situation in which a segment lacks a value in underlying or intermediate representation for a feature that it is specified for on the surface. Underspecification is often used, for example, in the lexical representation of harmonic affix vowels like those of the Turkish plural suffix (*-ler* ~ *-lar*), whose specification for [back] is completely predictable from the stem that the affix attaches to (*ev-ler* 'house-pl', *at-lar* 'horse-pl'); there is no evidence that the suffix vowel has any intrinsic [back] specification of its own to lexically store. Phonetic underspecification is the situation in which a segment lacks a phonological feature value, and therefore a phonetic target, for some dimension that other similar segments in the language can be specified for. This is invoked especially frequently for tone in languages where only a relatively few syllables in a word have a clear phonetic tonal target and the others assimilate gradiently to the pitch of nearby targets; for example to describe English intonation, Liberman and Pierrehumbert (1984: 218) use H[igh] for high pitch targets and L[ow] for low ones in sentences such as *Is it five?*, which has an L associated with *Is* and an H associated with *five*; the pitch contour of the middle word, *it*, is simply the transition between L and H, with no tonal target of its own.

Generally, a given token of a segment is considered underspecified with respect to a binary-valued feature only if it is legal generally for segments of that type to bear the feature in question; thus, for example, vowels are not normally considered underspecified for features that only consonants can bear (e.g.,

Underspecification

S Inkelas, University of California, Berkeley, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

Underspecification in phonology is the partial description of lexical entries, intermediate forms (phonological underspecification) or surface forms (phonetic underspecification). Motivations for underspecification range from language-particular descriptive necessity to the desire to capture universal phonological generalizations.

Underspecification is a relative notion, defined by the absence of specification in any given form for features or metrical structures that play an active role in the language. Phonological underspecification is the situation in which a segment lacks a value in underlying or intermediate representation for a feature that it is specified for on the surface. Underspecification is often used, for example, in the lexical representation of harmonic affix vowels like those of the Turkish plural suffix (*-ler* ~ *-lar*), whose specification for [back] is completely predictable from the stem that the affix attaches to (*ev-ler* 'house-pl', *at-lar* 'horse-pl'); there is no evidence that the suffix vowel has any intrinsic [back] specification of its own to lexically store. Phonetic underspecification is the situation in which a segment lacks a phonological feature value, and therefore a phonetic target, for some dimension that other similar segments in the language can be specified for. This is invoked especially frequently for tone in languages where only a relatively few syllables in a word have a clear phonetic tonal target and the others assimilate gradiently to the pitch of nearby targets; for example to describe English intonation, Liberman and Pierrehumbert (1984: 218) use H[igh] for high pitch targets and L[ow] for low ones in sentences such as *Is it five?*, which has an L associated with *Is* and an H associated with *five*; the pitch contour of the middle word, *it*, is simply the transition between L and H, with no tonal target of its own.

Generally, a given token of a segment is considered underspecified with respect to a binary-valued feature only if it is legal generally for segments of that type to bear the feature in question; thus, for example, vowels are not normally considered underspecified for features that only consonants can bear (e.g.,

[strident]), and vice versa. Most discussions of underspecification in the literature are confined to segmental or tonal features.

Surface (Phonetic) Underspecification: Gradient Interpolation

Surface underspecification is used to capture the phonetic contrast between segments that are associated with a target for some articulatory dimension and those that are not. The former show consistent behavior along the dimension in question; the latter are fully characterized through coarticulation with, or interpolation between, the phonetic targets associated with segments to either side. A case of tonal interpolation in a pitch-accent language is discussed by Pierrehumbert and Beckman (1988), who distinguish vowels that have High or Low tonal targets in Japanese from tonally underspecified vowels. The pitch of a tonally underspecified vowel is predicted from its location on the transitional curve connecting the pitches of the tonal targets on either side. Similar interpolation in the segmental domain is discussed by Keating (e.g., Keating, 1988), who shows that in terms of tongue shape features, /h/ coarticulates fully in with the segments on either side, rather than establishing any place of articulation targets of its own. Cohn (1990) found parallels in the nasal dimension in many languages, arguing against surface specification of [nasal] or [oral] for segments whose nasal airflow is best described as a steady, gradual transition from the degree of nasal airflow found in the fully specified segments to either side, whatever they might be.

Uses of Phonological Underspecification

Even for segments that are fully specified on the surface and have clear phonetic targets for particular features, there are arguments for underspecification at underlying or intermediate representation. A variety of arguments have been put forward for underspecification, not all of them mutually consistent.

Economy Metric

The first general use of underspecification in the generative literature was in service of lexical economy. Chomsky and Halle (1968) proposed an evaluation metric based on feature-counting that favors forms whose underlying featural description is minimal; thus, for example, the underlying representation of a form whose phonetic realization is [sæt] might be missing the [-voice] specification for [s] and [t], the [-back] specification for [æ], and so forth; these would be supplied, possibly immediately, by the phonological rules of the grammar. Lexical economy has largely fallen out of favor as the motivation for underspecification, however, yielding to approaches that use underspecification to capture patterns of phonological behavior either cross-linguistically or in a particular language.

Capturing Markedness

In the early 1980s underspecification was adopted as a means of capturing cross-linguistic generalizations about markedness. Marked feature values are more restricted in their distribution and tend to be more involved in triggering phonological alternations. Operating on the strong assumption, building on earlier work from the Prague school of linguistics, that for every binary-valued feature, in any given context, there is one marked and one unmarked value, Kiparsky (e.g., 1982) and Archangeli (e.g., 1984) developed the theory of Radical Underspecification in which the universally unmarked value of any given feature value is automatically underspecified in the lexicon of every language. For vowels, [+high] is unmarked and therefore underspecified; for obstruents, [-cont] is unmarked and therefore underspecified, and so forth. As a result of underspecification, phonological rules can refer to and manipulate only marked feature values during the stage of the derivation when underspecification is in force, accounting for the greater relative activity of marked feature values and for the greater tendency of segments with unmarked feature values to assimilate to other, more marked segments (thus, for example, coronal consonants, whose place of articulation is considered unmarked relative to labials, palatals, and velars, are the most likely of all consonants to assimilate in place to a neighboring consonant; underspecifying them for place permits the researcher to formally model this asymmetry). In Radical Underspecification Theory, underspecified values are filled in at a late stage of the derivation, at which point the behavioral asymmetry between marked and unmarked feature values disappears.

Radical Underspecification Theory can be modified to capture language-particular markedness as well as universal markedness by taking context into account. The value that may be unmarked for a given feature in general – e.g., [-voice], for obstruents – may be the marked value in a specific context – e.g., postnasally, for obstruents.

The universality of Radical Underspecification has been challenged by observations that markedness itself is not completely universal; what qualifies as the unmarked, or default, vowel or consonant can vary across languages. The use of underspecification

to capture unmarkedness in general has also been challenged by arguments initiated by Steriade (1995) and furthered in Optimality Theory (Prince and Smolensky, 1993), that grammatical constraints, rather than differentially specified representations, are the best means of handling markedness effects. For example, Pulleyblank (in press) argued that the special status of /i/ in Yoruba, which in a 1988 paper he attributed to unmarkedness and total featural underspecification, is better captured through grammatical constraints and does not require full specification of /i/. Pulleyblank argued that underspecification of /i/ is not just superfluous but actually interferes with the proper analysis of Yoruba phonology, citing several phonological patterns (e.g., /r/ deletion between identical vowels) that must specifically refer to the features of /i/. Such patterns are incompatible with underspecification. A recent comprehensive discussion of markedness in Optimality Theory is presented in DeLacy (2002).

Predicting Contrast

Not only are universally unmarked feature values relatively inactive, relative to universally marked features; features that are not contrastive in a particular environment within a language have also been claimed to play less of a role in conditioning or triggering alternations. Contrastive underspecification theory, developed by Mester and Itô (1989), uses underspecification to capture behavioral differences between contrastive and redundant features. According to Contrastive Underspecification Theory, feature values are fully specified on all segments of a type for which a given feature is contrastive and underspecified on segments in a class within which the feature is not contrastive. Thus, for example, [voice] would be specified on all obstruents in Japanese, which distinguishes [t] and [d], but not on sonorants, which are uniformly voiced; Mester and Itô utilize contrastive underspecification for voice to account for why Rendaku compound voicing in Japanese (*ori* + *kami* → *origami*) is impeded by contrastive obstruent voicing in the second member of the compound (e.g., *kami* + *kaze* → *kamikaze, not *kamigaze*) but not (redundant) sonorant voicing, as in *origami* (not **orikami)*. Mester and Itô proposed a ban on multiple specifications of [+voice] in the second member of the compound; *-gaze,* with voiced [g] and [z], would violate this ban, but *-gami* would not, on the view that the redundant voicing on [m] is not phonologically represented.

As with Radical Underspecification, Contrastive Underspecification has met with empirical and theoretical challenges. In Japanese, for example, other language evidence suggests that sonorants must be specified for [voice] in the lexical representation. And the nonrepresentational methods of differentiating contrastive and redundant feature values made available in Optimality Theory have reduced or eliminated appeals to contrastive underspecification.

Archiphonemic Underspecification

The use of underspecification which has been the most resilient to empirical and theoretical challenge, is in the description of highly language-specific patterns, of two related kinds: (a) the featural content of a segment is completely predictable from context, with no evidence bearing on its lexical featural specification, if any, and (b) there is a three-way contrast among segments, such that some are clearly specified for one value of a binary-valued feature, others are clearly specified for the opposite value of that feature, and the others oscillate between the two values, according to context. In Turkish, for example, most suffix vowels are harmonic; their values for [back] and [round] are always predictable from context. Assigning these vowels a lexical value of their own would be purely arbitrary, and most descriptions of Turkish in the literature opt not to do this. This use of underspecification is conceptually equivalent to the structuralist 'archiphoneme.' Turkish also has nonharmonic suffix vowels: some are always front (e.g., *-ken* 'while doing/being,' as in *çocuk-ken* 'while a child'), and others are always back (e.g., the second vowel in the progressive suffix *-Iyor*, as in *gel-iyor* 'is coming.' Archiphonemic underspecification has largely flown under the radar of universalist theories of underspecification, such as Radical or Contrastive Underspecification, to the point that rejections of the latter theories were voiced as rejections of underspecification of any kind (Steriade, 1995). However, recognition of the need for archiphonemic underspecification has been growing again in recent literature (Inkelas, 1995; Reiss, 2003).

Understanding Spoken Discourse

F Cornish, University of Toulouse-Le Mirail, Toulouse, France

Introduction: the Contextual Specificity of Spoken Interaction

To characterize spoken discourse requires us to specify the very different contexts of utterance which occur in the production and reception of spoken and written discourse. These configurations largely explain the rather different properties of spoken and written discourse, even allowing for equivalence of register and formality: see the well-documented account of crosslanguage spoken syntax and discourse in Miller and Weinert (1998).

Speech prototypically involves face-to-face interaction between two or more participants who share a spatiotemporal environment. This, together with a common cultural and personal background in the case of conversationalists who know each other well, provides a rich contextual common ground, allowing the speaker to avoid having to verbalize a number of aspects of his or her message. At the same time this common ground enables the discourse participants to rely to a large extent on nonverbal signaling, in tandem with and even, on occasion, in place of, the verbal textualization of a given utterance. Planning time, as well as 'understanding' time, is naturally minimal and at a premium – and a great many features of spontaneous speech flow from this key factor. Moreover, both speech and writing are normally designed by the user so as to be readily understood by the addressee (cf. the notion of 'recipient design'). Indeed, according to Clark (1996) and other linguists, conversation and communication in general is a fundamentally joint activity, involving the active participation of the interlocutors and the coordination of their actions (verbal as well as nonverbal).

What I have just (very briefly) characterized is of course the prototypical instance of spoken interaction. There are obviously other less prototypical types of spoken discourse: for example, speaking on the telephone, where the participants share a time frame (adjusting for time zone differences when the call is international) but not a spatial one, where only two participants are involved, and where the communication is 'ear to ear' rather than face to face (no nonvocal gestures or visual percepts are possible): see Drummond and Hopper (1991) for a discussion of miscommunication over the telephone; and speaking in a formal situation (a speech, lecture, and so forth) in front of a group of people in circumstances where convention does not normally allow for verbal exchange and interaction.

In written discourse, on the other hand, there is by definition no common spatiotemporal ground between the writer and his or her reader(s). Since this is the case, and since inevitably there will be little or no opportunity to use nonverbal signals, the text used will need to be relatively explicit – since the textual input is confined to the verbal content, in conjunction with punctuation and various graphic devices. The much greater availability, in principle,

Introduction: the Contextual Specificity of Spoken Interaction

To characterize spoken discourse requires us to specify the very different contexts of utterance which occur in the production and reception of spoken and written discourse. These configurations largely explain the rather different properties of spoken and written discourse, even allowing for equivalence of register and formality: see the well-documented account of crosslanguage spoken syntax and discourse in Miller and Weinert (1998).

Speech prototypically involves face-to-face interaction between two or more participants who share a spatiotemporal environment. This, together with a common cultural and personal background in the case of conversationalists who know each other well, provides a rich contextual common ground, allowing the speaker to avoid having to verbalize a number of aspects of his or her message. At the same time this common ground enables the discourse participants to rely to a large extent on nonverbal signaling, in tandem with and even, on occasion, in place of, the verbal textualization of a given utterance. Planning time, as well as 'understanding' time, is naturally minimal and at a premium – and a great many features of spontaneous speech flow from this key factor. Moreover, both speech and writing are normally designed by the user so as to be readily understood by the addressee (cf. the notion of 'recipient design'). Indeed, according to Clark (1996) and other linguists, conversation and communication in general is a fundamentally joint activity, involving the active participation of the interlocutors and the coordination of their actions (verbal as well as nonverbal).

What I have just (very briefly) characterized is of course the prototypical instance of spoken interaction. There are obviously other less prototypical types of spoken discourse: for example, speaking on the telephone, where the participants share a time frame (adjusting for time zone differences when the call is international) but not a spatial one, where only two participants are involved, and where the communication is 'ear to ear' rather than face to face (no nonvocal gestures or visual percepts are possible): see Drummond and Hopper (1991) for a discussion of miscommunication over the telephone; and speaking in a formal situation (a speech, lecture, and so forth) in front of a group of people in circumstances where convention does not normally allow for verbal exchange and interaction.

In written discourse, on the other hand, there is by definition no common spatiotemporal ground between the writer and his or her reader(s). Since this is the case, and since inevitably there will be little or no opportunity to use nonverbal signals, the text used will need to be relatively explicit – since the textual input is confined to the verbal content, in conjunction with punctuation and various graphic devices. The much greater availability, in principle,

of planning time allows the writer to review and to amend his or her written production.

The Context of Spoken Discourse, the Distinction between *Text* and *Discourse*, and their Roles in Understanding

It is useful in analyzing spoken (as well as written) discourse understanding to draw a three-way distinction between the dimensions of *text*, *discourse*, and *context*. Definitions which I find helpful are given below (see Cornish, 1999: §2.3 and 2003: §2 for further development and illustration of the 'text'/'discourse' distinction, and its importance for anaphora; also Edmondson, 1981: 4; Seidlhofer and Widdowson, 1999; and Werth, 1999: ch. 5 in connection with the notion 'context,' on 'Common Ground' within his 'Text Worlds' framework):

> *Text, discourse and context*
>
> *Text*: the connected sequence of verbal signs and nonverbal signals in terms of which discourse is coconstructed by the participants in the act of communication.
>
> *Discourse*: the hierarchically structured, situated sequence of indexical, propositional, utterance and illocutionary acts carried out in pursuance of some communicative goal, as integrated within a given context.
>
> The *context* is subject to an ongoing process of construction and revision as the discourse unfolds. It is through the invocation of a relevant context (which is partly determined by the nature of the cotext at issue, as well as by its genre) that the hearer or reader is able to convert the connected sequence of textual cues that is *text* into *discourse*. (Extract [slightly amended with permission from Mouton de Gruyter] from Cornish, 2003: 3.)

The text is the perceptible record of at least one utterance act (whether realized in terms of a verbal, linguistic trace or of a nonverbal trace – which may be gestural, sensory-perceptual or prosodic). See especially Clark (1996), chapter 6, on nonverbal signals and their different kinds of function in discourse. Clark draws a highly relevant distinction between two simultaneously functioning textual 'tracks' which operate in spoken discourse: a primary track, where the 'official business' of the transaction at hand is conducted; and a secondary 'metadiscursive' or discourse management track, where participants make explicit the purposes and functions of the preceding and ongoing talk. The functions of either track may be realized via verbal and nonverbal signals (whether in tandem or individually). We shall be looking at examples of this dual-track structure in operation shortly.

The notion of *text* is close to what Gumperz (1992: 234) calls "contextualization cues." The discourse partners make use of this record (a dual-track one, according to Clark, 1996), in conjunction with their invocation of a relevant *context* in cognitive terms, in order to create discourse.

Discourse, on the other hand, refers to the hierarchically structured, mentally represented product of the sequences of utterance, propositional, illocutionary, and indexical acts which the participants are carrying out as the communication takes place. Such sequences have as their *raison d'être* the accomplishment of some particular overall communicative goal (see Parisi and Castelfranchi, 1977).

The crucial point about this distinction is that discourse is a (re)constructive, and therefore highly probabilistic, enterprise: from the addressee's perspective, it is by no means a question of simply directly **decoding** the text in order to arrive at the fully fledged message originally intended by the addressor. Indeed, the addressee actively contributes both to the text and to the discourse via his or her phatic signals, indications of (mis)understanding, and other reactions to the speaker's moves. Meaning does not lie 'in' the text; it has to be constructed by the addressee (and the speaker!) via the text and an appropriate context (cf. Coupland *et al.*, 1991: 5). In any case, the text is often, if not always, both incomplete and indeterminate in relation to the discourse which may be derived from it in conjunction with a context.

Some Aspects of Understanding Spoken Discourse

Inferring Propositional Content and Illocutionary Force

In what follows, I shall be examining instances of (mis)understanding which occur, and are manifest, **within** conversations. So it is the monitoring by the discourse participants themselves of the discourse being co-constructed that is at issue here. I am adopting the principle that it is when misunderstandings, disagreements, or disruptions generally are manifest in the textual record of a conversation that the way in which discourse normally operates may be seen most clearly (cf. Coupland *et al.*, 1991). Let us analyze an initial occurrence of such a phenomenon. Here is a segment from the BBC Radio 4 cultural discussion program *Start the Week*. The previous speaker (Caroline Quinn) has been arguing that the alienation of black people in the United States is not due to a single factor, but has a variety of causes; that the situation is improving for all racial groups in the United States, and that differences in degrees of

integration into U.S. society are in part due to differences in the 'cultural inheritance' which each group brings with it. Homi Bhabha is then given the floor (for a second time) by the presenter, Melvyn Bragg. Notational symbols used here are as follows: – : pause; — : double pause; upper-case letters: strongly accented syllable; [...]: simultaneous speech; = : latching; (a): elision of 'a'; .hhh = sharp intake of breath. See Cameron (2001), chapter 3 and Schiffrin (1994), Appendix 2 for details of spoken discourse transcription.

> HB: Kate Kate – Caroline – you know I'm SURE you didn't mean it but sometimes – cultural inheritance shades off into biological inheritance – in in the States you know people say .hhh – Blacks are in some – inherent way – inferior – an' there's a lot of – a lot of a lot of stuff going around now of course – American Blacks came as slaves it's not what they brought with them it was what they were not – Able to bring with them they were [snatched – no but – —]
> CQ: [it's no – it's nobody's fault] =
> Idem: = no I'm not saying it's anybody's fault – but I'm just saying you know that that's the brute – historical – FACT . . .

In track 1 here, Caroline Quinn asserts that the fact that black slaves were forced to sail to America without taking any of their possessions with them was not **their** fault (this is the proposition actually intended to be conveyed by the speaker here). It is no doubt the extreme sensitivity of the issue (racism towards Blacks) that has motivated the use of the indefinite negative with wide scope, *nobody*, here. (This is also the motivation for HB's intake of breath in line 4, just before his presentation of the [racist] view of Blacks in the United States.) And in track 2, the same speaker is rejecting what she sees as Homi Bhabha's illocutionary stance in the extract – justifying and even seeming to condone the fact that black people in the United States are still not considered as 'real' Americans. Bhabha's response (in track 2) is to assert that this is not **his** view (notice his repetition of the verb *say* in "I'm (not) saying . . . "), but that the source of the way black Americans are viewed today is an objective, historical fact; and in doing so, he is clearly rejecting Caroline Quinn's implied interpretation of his illocutionary stance in his first turn.

Inferring Intended Interactional Moves and Acts

Occasionally, speakers and their addressee(s) disengage themselves from the discourse which they are creating, to establish metadiscursively what the relation is between their adjacent moves. This occurs in the 'second' track, then, in Clark's (1996) terms. When this happens, we get an explicit view of how the discourse participants are interpreting each other's utterances (see also Cameron, 2001: 116). An example occurred during a discussion about the Devil in another edition of *Start the Week* (April 22, 1996). Here, Melvyn Bragg (MB) is picking up on Peter Stanford's characterization of the use of 'the Devil' by the medieval Church as a means of social control:

> MB: yes – the interesting thing is that was it already coercive an' repressive – or did it actually call out something that's in people anyway – I mean the way you put it is that this is an authorit this is a Church behaving as the Church behaved in many many diff(e)rent ways – in great ways an' in wicked ways – but this is a Church behaving in a very authoriTArian way – in saying "you will follow us – or we will er – we will – get you and we've got the man to get you – he's called 'the Devil' " – but – isn't there something else there – isn't it a rec(og)nition of what's part of human nature and it was a BRILLiant metaphor – just as Christianity is full of brilliant metaphors as to what human nature is about so – .hhh it's more positive in a way than [what you're saying]
> PS: [well – well] it wouldn't have worked would it – un un unless they were actually tapping into something that people wanted to believe – and if you think about it =
> MB: = so you're agreeing =
> PS: = I'm agreeing – but if you think about the – concept of evil . . .

Melvyn Bragg, in his first turn, is objecting to what he sees as a one-sided view of the status of the Devil in the medieval Church, according to Peter Stanford's earlier characterization: he is taking the view that, rather than 'imposing' the Devil on believers in an authoritarian manner, the medieval Church more intelligently used the Devil as a metaphor for something that it recognized as already being part of human nature. Given that it is the former view which Bragg understands Stanford to be adopting, he clearly expects him to disagree with his objection. Yet Stanford's response is in conformity with this 'objection,' so it cannot count as a 'disagreement.' As soon as Bragg realizes this, he interrupts Stanford's response and asks him (via a declarative request) for confirmation of this interpretation. Stanford then immediately gives it by repeating the 'agreement' statement, then moves straight on to a development of the main point he had begun making at the point of interruption. This is achieved via a repetition of the actual words of his preceding final utterance (with the conjunction *and* replaced by the adversative *but*): . . . *and if you think about it* . . . . This is clear evidence of the 'two-track' structure of textual development, as argued by Clark (1996), since the final conjunct of the

preinterrupted segment by Peter Stanford is repeated virtually verbatim immediately after the interruption. This indicates that the primary, 'official business' track has not in fact been interrupted, but that it is the secondary, metadiscursive one which contained the interruption.

Conclusion

As Clark (1996) in particular emphasizes throughout his book, discourse is a joint endeavor, not the individual responsibility of the speaker, where the addressee has a merely passive role in decoding his or her utterances. The textual record (verbal content of the utterances as well as meaningful gestures, prosody, and phatic and other vocalizations) underdetermines the discourse which the participants are jointly constructing as the text unfolds in a particular context. The discourse constructed at any given point in this unfolding is a tentative, probabilistic affair, and not only is it subject to continual modification in terms of updating as each new utterance is encountered, but the immediately preceding discourse at a given point may also be revised and reconstructed retroactively, as a function of a subsequent discourse act or move. This may occur when a participant, encountering another's reaction to what he or she is attempting to say, realizes the latter has misunderstood his or her propositional content or illocutionary stance or the nature of his or her move (see the *Start the Week* examples above). In triggering this process of updating, revision and (re)negotiation, discourse particles, vocal and visual gestures, pausing and prosody generally, all take on a crucial significance. The dual-track structure of textualization suggested by Clark (1996) makes possible this parallel management of the discharge of 'official discourse business' (track 1) on the one hand, and the signaling of discourse organization (track 2) on the other.

Writing a context-free grammar for a (fragment of) natural language can be a rather tedious and linguistically nongratifying job. Some phenomena, such as agreement, are hard to describe using the standard machinery of context-free grammar. Other phenomena, such as the grammar of *wh*-movement, may even seem impossible to implement.

A related problem comes from the development of (wide-coverage) lexica for formal or computational grammars. Grammars for natural language tend to make quite detailed assumptions about the information available in lexical entries. While for theoretical purposes it may suffice to specify which type of information one considers to be lexical, a lexicon that needs to be used in practical applications actually has to provide this information, usually for a large number of lexical items. Although the amount of information that has to be present in individual lexical items can be substantial, the differences between large groups of lexical items are often small and predictable. This suggests that lexica for computational grammars can and should employ mechanisms that ensure that information can be shared among lexical items.

For these reasons, the use of feature-based grammar formalisms, which employ unification as the sole mode for sharing and checking information, has become widespread, both in theoretical linguistics and in computational linguistics. Unification grammar allows for concise descriptions of agreement and other phenomena, including constructions that are beyond the descriptive power of context-free grammar. Lexical items can be associated with information-rich feature structures. Commonalities between these structures can be expressed using inheritance.

Linguists have always felt the need to use indices, variables, and features in their theoretical frameworks. Unification grammar provides the formal underpinning for these notational devices, which are often presented as straightforward extensions of context-free grammar. Unification is also the cornerstone of a family of linguistic theories, such as lexical functional grammar (Bresnan, 1982), generalized phrase structure grammar (GPSG; Gazdar *et al*., 1985), and head-driven phrase structure grammar (HPSG; Pollard and Sag, 1994) and has been applied fruitfully to categorial grammar and tree-adjoining grammar. What all these frameworks have in common is that they encode linguistic knowledge (rules, principles, lexical entries, etc.) in the form of feature structures and that unification is used as the operation to combine information. Unification can be implemented efficiently, and most parsing algorithms for context-free grammar can be extended easily to unification-based grammars. Unification-based grammars are therefore popular in natural language processing, especially in work that emphasizes linguistic aspects.

Basic Notions

Feature structures, as shown in Figure 1, consist of features and values. Values can be either atoms or feature structures themselves. The feature structure in Figure 1A contains a feature CAT, whose value is the atom *np*, and a feature AGR, whose value is a feature structure specifying values for NUM and PER. The path ⟨AGR PER⟩ refers to the value of the feature PER within the feature structure that is the value of AGR. The value of ⟨AGR PER⟩ in the feature structure in Figure 1A is the atom *1st*. Feature structures may also contain reentrancies, stating that the value of two or more features is shared. This is usually indicated by prefixing the shared values with a boxed integer. The actual value of the reentrant features is mentioned only once. The feature structure in Figure 1B contains a reentrancy for ⟨SUBJ⟩ and ⟨COMPL SUBJ⟩. The value of both paths is the atom *kim*.

Feature structures may be partially ordered according to the amount of information they contain. If feature structure A is more general than B, that is, if all the information in A is also present in B, then A subsumes B.

Definition 1 *Feature structure A* **subsumes** *feature structure B if and only if (iff)*

- *For every feature F in A,*
  – if the value of F in A is atomic, the value of F in A and B is identical,
  – if the value of F in A is a feature structure, the value of F in A subsumes the value of F in B.
- *Every reentrancy in A is also present in B.*

$$\textbf{A}\quad \begin{bmatrix} \text{CAT} & np \\ \text{AGR} & \begin{bmatrix} \text{NUM} & pl \\ \text{PER} & 1st \end{bmatrix} \end{bmatrix} \qquad \textbf{B}\quad \begin{bmatrix} \text{SUBJ} & \boxed{1}\ kim \\ \text{COMPL} & \begin{bmatrix} \text{SUBJ} & \boxed{1} \end{bmatrix} \end{bmatrix}$$

Figure 1 Feature structures (A) containing a feature with another feature structure as value and (B) containing a reentrancy.

Unification is the operation that merges two feature structures into a single feature structure containing all the information encoded in the two input structures and nothing more. If the two input structures contain conflicting information, unification fails. Unification is defined in terms of subsumption:

Definition 2 *The* **unification** *of feature structures A and B is the most general feature structure that is subsumed by both A and B, if such a feature structure exists.*

Unification-Based Grammar

A unification-based grammar consists of a lexicon, in which each word is associated with one or more feature structures, and grammar rules, also defined in terms of feature structures. In the simplest case, grammar rules are comparable to those of context-free grammar in the sense that they consist of a mother and an ordered list of (zero or more) daughters. That is, the rule in Figure 2 will allow for the derivation of a constituent of category S (i.e., with feature structure [CAT *s*]) only if there is a constituent that is unifiable with the first feature structure on the right-hand side of the arrow, followed by a constituent that is unifiable with the second feature structure on the right-hand side. The reentrancy for the feature AGR between the two daughters requires that the whole rule must in fact be understood as expressing a single feature structure. This is shown in Figure 2B. Note that the list of daughters is expressed as a (recursive) feature structure, in which FIRST is used to denote the value of the first element of a list and REST to denote the value of the tail of a list.

Unification-based grammars are often referred to as constraint-based grammars. A grammar defines the feature structures that are associated with lexical items and grammar rules. In doing so, the grammar has to use a language for describing feature structures. Following Kasper and Rounds (1986) and others, a language for feature structures can be given a semantics by specifying which feature structures satisfy a given description. Descriptions can also be seen as imposing constraints on the feature structures that satisfy them. For this reason, unification-based formalisms are often referred to as 'constraint-based grammar formalisms.' In the simplest feature description languages, one can describe a feature structure only as a conjunction of statements that specify an atomic value for a path or a reentrancy between paths. In such languages, there is always a unique feature structure satisfying a description that subsumes all other features structures satisfying the description. More powerful languages allow for disjunction and negation; that is, one may state that the value of CASE is *nom* or *acc* or *not gen*. Languages that are even more powerful allow the use of quantification and relations. In such languages, one may state that all elements in a listlike feature structure have to meet a certain requirement, or one may define the value of a feature as the append of two listlike feature structures. In these more powerful languages, there is no longer a unique most general feature structure satisfying a constraint, which may pose considerable challenges for implementation.

A

$$\begin{bmatrix}\text{CAT} & s\end{bmatrix} \rightarrow \begin{bmatrix}\text{CAT} & np \\ \text{AGR} & \boxed{1}\end{bmatrix}\begin{bmatrix}\text{CAT} & vp \\ \text{AGR} & \boxed{1}\end{bmatrix}$$

B

$$\begin{bmatrix}\text{MOTHER} & \begin{bmatrix}\text{CAT} & s\end{bmatrix} \\ \text{DAUGHTERS} & \begin{bmatrix}\text{FIRST} & \begin{bmatrix}\text{CAT} & np \\ \text{AGR} & \boxed{1}\end{bmatrix} \\ \text{REST} & \begin{bmatrix}\text{FIRST} & \begin{bmatrix}\text{CAT} & vp \\ \text{AGR} & \boxed{1}\end{bmatrix} \\ \text{REST} & nil\end{bmatrix}\end{bmatrix}\end{bmatrix}$$

Figure 2 Rules in a unification-based extension of context-free grammar can be interpreted as feature structures, consisting of a mother and a list of daughters.

Agreement as Unification

The advantages of using unification in grammar can be demonstrated easily with an example based on agreement. Dutch nouns have either neuter or non-neuter gender. The definite determiners *het* and *de* select for neuter and non-neuter nouns, respectively. The indefinite determiner *een* may be used with both neuter and non-neuter nouns. Prenominal adjectives are normally inflected, but an uninflected adjective occurs when the adjective modifies a (singular) neuter noun and the NP as a whole is indefinite (i.e., introduced by *een*):

(1a)	de	oude	kerk
	the	old	*church*(NNEUT)
(1b)	het	oude	huis
	the	*old*	*house*(NEUT)
(1c)	een	oude	kerk
	an	*old*	*church*
(1d)	een	oud	huis
	an	*old*	*house*

This agreement pattern is captured by the grammar fragment in Figure 3. Agreement is expressed by the feature AGR, which contains a feature GEN, used to capture the gender distinction, and DEF, used to distinguish between definite and indefinite NPs.

The determiner, adjective, and noun all may impose constraints on AGR. Unifying the value for AGR between noun and adjective and between the projection of a noun and the determiner enforces a requirement that agreement information contributed by all elements must be compatible. The fragment can be extended easily to take plurals into account.

It should be noted that the unification-based account of this phenomenon has several advantages over an account using only the standard machinery of context-free grammar. As there are four possible combinations of gender and definiteness values, a context-free grammar with atomic category symbols only would have to provide four variants for the two rules in Figure 3A and also two lexical entries for the indefinite determiner *een* (which combines with both neuter and non-neuter nouns). (Below, a technique is mentioned that allows the two lexical entries for *oude* to be reduced to one.) Note also that (undirectional) unification of information is essential in this case. An account based on upward or downward percolation of feature-values would have to ensure that information from the determiner can be passed on to the sister labeled [CAT *n*] and that information from the head noun can be passed on to the mother node as well as the sister labeled [CAT *a*]. A unification-based account can deal with this situation by simply assuming across-the-board sharing of the relevant morphosyntactic information.

Typed Feature Structures

It is customary to impose restrictions on the values that a given feature may take on. For instance, the value of CASE for a given grammar can be restricted to *nom*, *acc*, *dat*, or *gen*, while the value of NUM can be restricted to *pl* or *sg*. Similarly, one might want to impose constraints on which combinations of features can co-occur. For instance, the value of AGR could be restricted to feature structures which may contain the features PER and NUM but not CAT or SUBJ.

Typed feature structures make it possible to express such constraints. A typed feature structure is well formed only if it is in accordance with a type signature.

Definition 3 *A* **type signature** *consists of:*

- *A finite set of types,*
- *A partial order on types,*
- *Appropriateness conditions, specifying*
  - *the features that are appropriate for a given type,*
  - *the type of the values that each feature may take on.*

Figure 4 contains a fragment of a type signature. It defines the types *verb* and *noun* as subtypes of *sign*. For *sign* the attribute AGR is appropriate, and its value has to be of type *agr*. For nouns, an additional feature CASE is appropriate, and its value has to be of type

A

$$\begin{bmatrix}\text{CAT} & np\\ \text{AGR} & \boxed{1}\end{bmatrix} \rightarrow \begin{bmatrix}\text{CAT} & det\\ \text{AGR} & \boxed{1}\end{bmatrix}\begin{bmatrix}\text{CAT} & n\\ \text{AGR} & \boxed{1}\end{bmatrix}$$

$$\begin{bmatrix}\text{CAT} & n\\ \text{AGR} & \boxed{1}\end{bmatrix} \rightarrow \begin{bmatrix}\text{CAT} & a\\ \text{AGR} & \boxed{1}\end{bmatrix}\begin{bmatrix}\text{CAT} & n\\ \text{AGR} & \boxed{1}\end{bmatrix}$$

B

$$\text{de} \mapsto \begin{bmatrix}\text{CAT} & det\\ \text{AGR} & \begin{bmatrix}\text{DEF} & +\\ \text{GEN} & nneut\end{bmatrix}\end{bmatrix} \qquad \text{oude} \mapsto \begin{bmatrix}\text{CAT} & a\\ \text{AGR} & \begin{bmatrix}\text{GEN} & nneut\end{bmatrix}\end{bmatrix}$$

$$\text{het} \mapsto \begin{bmatrix}\text{CAT} & det\\ \text{AGR} & \begin{bmatrix}\text{DEF} & +\\ \text{GEN} & neut\end{bmatrix}\end{bmatrix} \qquad \text{oude} \mapsto \begin{bmatrix}\text{CAT} & a\\ \text{AGR} & \begin{bmatrix}\text{DEF} & +\\ \text{GEN} & neut\end{bmatrix}\end{bmatrix}$$

$$\text{een} \mapsto \begin{bmatrix}\text{CAT} & det\\ \text{AGR} & \begin{bmatrix}\text{DEF} & -\end{bmatrix}\end{bmatrix} \qquad \text{oud} \mapsto \begin{bmatrix}\text{CAT} & a\\ \text{AGR} & \begin{bmatrix}\text{DEF} & -\\ \text{GEN} & neut\end{bmatrix}\end{bmatrix}$$

$$\text{huis} \mapsto \begin{bmatrix}\text{CAT} & n\\ \text{AGR} & \begin{bmatrix}\text{GEN} & neut\end{bmatrix}\end{bmatrix} \qquad \text{kerk} \mapsto \begin{bmatrix}\text{CAT} & n\\ \text{AGR} & \begin{bmatrix}\text{GEN} & nneut\end{bmatrix}\end{bmatrix}$$

Figure 3 Rules and lexical entries for internal agreement of Dutch singular *nps*.

Figure 4 Fragment of a signature for a grammar with typed feature structures.

case. The subtypes of *case* are given as well. Note that no features are appropriate for *case* and its subtypes.

The definition of subsumption for typed feature structures takes type subsumption into account:

Definition 4 *A typed feature structure A* **subsumes** *a typed-feature structure B iff*

- *The type of A subsumes the type of B,*
- *For every feature F in A it is the case that the value of F subsumes the value of F in B,*
- *Every reentrancy present in A is also present in B.*

Note that, as all atomic values are types, the distinction between complex and atomic values is no longer relevant. The unification of two typed feature structures is the most general typed feature structure subsumed by both feature structures, if such a structure exists.

The use of types can make it easier to grasp a grammar. In implementations, types can be used to facilitate grammar maintenance (for instance by detecting errors at compile time) and to improve processing speed. Finally, types can be used to express generalizations that may be hard to express in an untyped system.

For instance, to capture the agreement in Dutch singular NPs described in the previous section, one might eliminate the features GEN and DEF and instead use the type hierarchy in Figure 5 as potential values for a feature AGR. The most specific types in the hierarchy express combinations of the value for definiteness and gender. The definite determiners *de* and *het* would be [AGR *neut-def*] and [AGR *nneut-def*], respectively. The intermediate types express a value for either definiteness or gender. The indefinite determiner is specified as [AGR *indef*], for instance, while nouns are [AGR *neut*] or [AGR *nneut*]. The type *nneut-or-def*, finally, is added in order to be able to describe the agreement properties of an inflected adjective (*oude*). An uninflected adjective would be [AGR *neut-indef*]. Note that by providing a single lexical entry for inflected adjectives, the use of types captures a generalization that is missed in the untyped fragment in Figure 3.

Inheritance and Default Unification

Unification-based formalisms use unification to combine feature structures encoding linguistic properties. Unification is a monotonic operation in the sense that it combines information and can never change or remove feature values. Monotonicity is in general a property to be appreciated: it supports declarative interpretations and implementations of grammar formalisms. Certain linguistic phenomena, however, are more easily described using default mechanisms of various sorts. This holds for lexical information in particular, but defaults have also been used in syntax.

Unification-based frameworks tend to organize the lexicon using some form of inheritance. All verbs have certain properties in common (i.e., they are of category *verb*, they may combine with a subject and zero or more complements, etc.), and these properties should preferably be stated only once. The idea of inheritance is to define a class or type (i.e., *verbal-lexeme*) that states that any element in this class has to be of category *verb*, etc. A lexical item that is defined to be of class *verbal-lexeme* inherits all the properties defined for this class. Classes may inherit from more general classes. Thus, one might define a class *transitive-verb* that inherits from *verbal-lexeme*. A snapshot of a hypothetical lexical hierarchy is given in Figure 6. Note that classes are similar to types in the sense that they are both partially ordered and impose constraints on feature structures. The distinction between types and classes is therefore often conflated.

The *verbal-lexeme* class in Figure 6 states that a verb may combine with a subject whose NFORM is *norm*. This statement will rule out sentences in which a verb combines with expletives such as *there* or *it*. While the statement is true for the majority of verbs, an intransitive verb such as *rain* is exceptional in that it selects for expletive *it*. If inheritance is a default mechanism, one can define *rains* as inheriting from *intransitive-verb* with the exception of the value for NORM, which is explicitly assigned the value *it* in the lexical entry of *rain*. Similarly, there are verbs that take a clausal subject or object. Such verbs can share certain properties with either intransitive or transitive

Figure 5 Type signature for agreement in Dutch NPs.

verbs. Thus, one might consider classifying them as either intransitive or transitive, but one must ensure at the same time that the value of ⟨SUBJ CAT⟩ or ⟨COMPS FIRST CAT⟩ is *s* instead of *np*.

It should be noticed that the feature structures in Figure 6 are artificially simple. Thus, while it may seem that in this case one could easily come up with an alternative hierarchy that is strictly monotonic, doing so will in general be harder for realistic examples. In that case, any attempt to encode a lexical hierarchy monotonically may lead to considerable reduplication of information.

The use of inheritance to capture generalizations is not restricted to the lexicon. HPSG, for instance, was originally seen as a theory that put strong emphasis on the lexicon while minimizing the number of phrase structure schemata. In more recent versions of this theory (Sag, 1997; Ginzburg and Sag, 2000), however, a substantial number of construction-specific phrase structure schemata are being used. Generalizations over various schemata are captured by means of inheritance.

A somewhat different reason for considering default mechanisms in syntax comes from observations concerning feature percolation. An important generalization about phrase structure rules is that the syntactic properties of a phrase are to a large extent determined by the syntactic properties of the head of that phrase. Authors differ, however, on whether this generalization is only a default (i.e., it holds for most syntactic properties and in most syntactic constructions, but exceptions exist) or a requirement that can be imposed without exception on a certain class of syntactic properties. In GPSG, for instance, the head-feature convention states that head features are identical on mother and head daughter unless there is information in the rule that contradicts this. Head features typically express morphosyntactic properties, such as agreement, case, verb form, etc. The head-feature principle of HPSG as formulated by Pollard and Sag (1994) states that the head features of the mother and head daughter in a rule are reentrant. This principle excludes any possibility of exceptions.

Figure 6 Fragment of a verbal lexical hierarchy.

The generalized head feature principle of Ginzburg and Sag (2000), finally, is again a default principle. Furthermore, it is no longer restricted to morphosyntactic information but applies to all syntactic and semantic information.

One might try to come up with specific operations on feature structures to implement the effects of default inheritance or the default interpretation of a head feature principle. It seems, however, that a more general solution can be found by extending the unification-based formalism with a nonmonotonic notion of unification. The specific mechanisms discussed above can ideally all be defined in terms of this general operation. Various proposals for a general default unification operation have been put forward. Bouma (1992) and Carpenter (1992b) both propose operations that nonmonotonically combine a feature structure D (contributing the default information) with a feature structure S (contributing strict information) in such a way that all information from S is preserved, as well as the information from D that is consistent with S. In terms of subsumption, one might define the default unification of D and S as the unification of D′ with S, where D′ is the maximally specific feature structure subsuming D and unifiable with S. Figure 7A illustrates default unification for a simple case not involving reentrancies, where we use $\sqcup!$ to denote the default unification operation.

Default unification of feature structures that do contain reentrancies is harder to define. Part of the problem is that there may be more than one way to generalize D to a feature structure D′ compatible with S. This is illustrated in Figure 7B. D in this case might be generalized in two different ways (i.e., by

$$\textbf{A}\quad D = \begin{bmatrix} \text{CASE} & \textit{nom} \\ \text{NFORM} & \textit{norm} \end{bmatrix} \qquad S = \begin{bmatrix} \text{NFORM} & \textit{it} \end{bmatrix}$$

$$D \sqcup\!! \, S = \begin{bmatrix} \text{CASE} & \textit{nom} \\ \text{NFORM} & \textit{it} \end{bmatrix}$$

$$\textbf{B}\quad D = \begin{bmatrix} \text{HEAD} & \boxed{1}\begin{bmatrix} \text{COMPL} & - \end{bmatrix} \\ \text{HD-DGHTR} & \begin{bmatrix} \text{HEAD} & \boxed{1} \end{bmatrix} \end{bmatrix} \qquad S = \begin{bmatrix} \text{HEAD} & \begin{bmatrix} \text{COMPL} & + \end{bmatrix} \end{bmatrix}$$

$$\textbf{C}\quad D \sqcup\!! \, S = \begin{bmatrix} \text{HEAD} & \boxed{1}\begin{bmatrix} \text{COMPL} & + \end{bmatrix} \\ \text{HD-DGHTR} & \begin{bmatrix} \text{HEAD} & \boxed{1} \end{bmatrix} \end{bmatrix}$$

$$\textbf{D}\quad D \sqcup\!! \, S = \begin{bmatrix} \text{HEAD} & \begin{bmatrix} \text{COMPL} & + \end{bmatrix} \\ \text{HD-DGHTR} & \begin{bmatrix} \text{HEAD} & \begin{bmatrix} \text{COMPL} & - \end{bmatrix} \end{bmatrix} \end{bmatrix}$$

Figure 7 Default unification examples.

removing [COMPL −] or by removing the reentrancy), leading to the result in Figure 7C and 7D, respectively. Carpenter's 'credulous default unification' (1992b) defines the result of default unification in such cases as a disjunction of possibilities. His 'skeptical default unification' defines the result as the maximal feature structure subsuming all the disjuncts obtained by 'credulous default unification.' Bouma's (1992) default unification does define D′ as the maximal specific generalization of D that does not contain paths with an atomic value or reentrant paths that are mentioned in S. In general, this suppresses more information from D than would be required by the consistency requirement. On the other hand, it does allow one to suppress information (i.e., to generalize a feature structure) by means of default unification. One application is the definition of auxiliary verbs in theories like HPSG. Auxiliaries may combine with any type of subject (i.e., normal and expletive NPs as well as sentential subjects) as long as they do so in accordance with the selection requirements of the main verb heading the VP selected by the auxiliary. This dependency is expressed by the provision of strict information that the value of SUBJ is reentrant with the SUBJ value of the VP-complement. Furthermore, the normal, default value for SUBJ is suppressed.

Following earlier work by Young and Rounds (1993), Lascarides *et al.* (1996) and Lascarides and Copestake (1999) developed a notion of default unification for typed feature structures. It differs from other proposals in that it assumes that certain feature values are explicitly marked as default values. Default unification of two feature structures may never lead to conflicts in the nondefault values and, for features with a default value, preserves the value provided by the feature structure with the most specific type.

Default unification is usually seen as a means to streamline the definition of grammars. It allows one to express generalizations over classes of lexical items or grammar rules, and at the same time it does not exclude the possibility of exceptions to these generalizations. The interaction between default and strict information in grammar definitions can be computed off-line. That is, once a definition is complete, all information associated with a lexical item or phrase structure rule can be computed. During processing, however, the distinction between default and strict information is no longer relevant, and only monotonic unification is used. The proposal by Lascarides and Copestake (1999) is more radical in that it assumes that the interaction between default and strict information is not necessarily restricted to the definitional stage but may be preserved during processing.

Open Problems and Alternatives

Unification-based grammars, and especially unification-based approaches to morphosyntactic phenomena, have impressive empirical coverage. This is not to say that there are no open problems, however. Ingria (1990) argued that a typical unification-based account of agreement and case assignment makes the wrong prediction in cases such as (2).

(2a)	*sie	findet	und	hilft
	she	*finds*(ACC)	*and*	*helps*(DAT)
		Männer/	Männern	
		men(ACC)	*men*(DAT)	
(2b)	er	findet	und	hilft
	he	*finds*(ACC)	*and*	*helps*(DAT)
		Frauen		
		women		
		(DAT/ACC)		

The ungrammaticality of example (2a) suggests that the case of the direct object must be compatible with the case requirements of both coordinated verbs. A unification-based account would predict this by simply unifying the case values of both verbs with that of the direct object. The grammaticality of (2b) suggests that this cannot be the full story, however. If the direct object neutralizes the distinction between ACC and DAT, the sentence is grammatical. This suggests that the relation between the case requirements of the verbs and the case value of the object should not be modeled in terms of unification.

Coordination of unlike categories, as in (3), poses another challenge for unification-based approaches.

(3) Kim became wealthy and a Republican

Coordination of an AP and an NP is allowed only if the result is selected by a head that may combine with either an AP or an NP. Bayer (1996) argued that unification-based accounts of this phenomenon make the wrong predictions in a number of cases and argues for an account based on the proof system of Lambek categorial grammar. Johnson (1999) argued for a reformulation of lexical functional grammar that is similar in spirit to the proposal of Bayer.

Conclusion

Unification-based approaches to syntax have given rise to a family of linguistic frameworks that combine formal and descriptive precision and have served as the basis of various large-scale grammar implementation efforts.

Unification-based approaches to phonology and morphology have been developed as well (see Bird, 1995 and Riehemann, 1998). The use of unification in semantics was initially seen as more problematic (Moore, 1989), but the recent interest in formalisms for underspecified semantics (starting with Reyle, 1993 and Alshawi and Crouch, 1992) is heavily influenced by techniques from unification-based grammar.

More recently, computational linguistics has started to investigate combinations of unification-based grammars with stochastic models (Abney, 1997; Geman and Johnson, 2002). Such models typically use frequencies derived from large (annotated or unannotated) corpora to estimate probabilities for parses produced by a (wide-coverage) unification-based grammar.

Motivation

Early attempts to formally describe the structure of natural languages (Chomsky, 1956) resulted in the development of formal grammars, of which context-free grammars (CFGs) are a notable example. Context-free grammars, however, have been found inadequate for this purpose, not only because some natural languages are, apparently, beyond the expressive power of CFGs (Shieber, 1985; Manaster-Ramer, 1987), but also because CFGs do not provide sufficiently succinct descriptions of the phenomena linguists are usually interested in. The main drawback of CFGs (and other phrase-structure formalisms, including early incarnations of tree-adjoining grammars (Joshi *et al.*, 1975)) in this respect is that the symbols they manipulate are 'atomic,' with no inherent structure, whereas the linguistic entities that have to be modeled by them are inherently structured. For example, words have properties such as number, gender, tense or root; phrases are categorized and subcategorized; phonemes are described as sets of features; etc.

A natural way of extending phrase-structure grammars to rectify this problem is by incorporating 'properties' of symbols into the grammar, further specifying the crude categorial information. This is achieved by replacing the atomic symbols of CFGs by 'feature structures,' which provide a natural representation for the kind of linguistic information grammars specify. In this view, the lexicon associates with each word a set of feature structures, rather than a set of atomic terminal symbols, and grammar rules are defined over feature structures, rather than over atomic nonterminal symbols. With this extension, rule application has to be amended, too, and comparing two symbols cannot be simply reduced to identity checking, as is the case in CFGs. Rather, an information comparison and combination operation, 'unification,' is used to decide whether a rule can be applied to some form. This article defines feature structures (the second section), unification (the third section) and unification grammars (the fourth section) from a computational point of view. For a more linguistically oriented discussion of unification and default unification, refer to Bouma (**Unification, Classical and Default**).

The move from CFGs to unification grammars provides an additional dimension for linguistic generalizations. It facilitates the expression of linguistic constraints by means of a single rule, instead of a collection of 'similar' rules. More significantly, it also results in a dramatic increase in expressive power: the set of languages that can be defined by unification grammars is much larger than the set of context-free languages; in terms of the Chomsky (1956) hierarchy of languages, this is the set of recursively enumerable (type-0) languages. Consequently, computational processing of unification grammars is significantly less efficient than processing with CFGs. Some of these issues are discussed in the last section.

Feature Structures

Attribute-Value Matrices

Feature structures are graphically represented using a notation known as attribute-value matrices (AVMs). Such matrices list, within square brackets, a set of features, along with their values. Each 'row' in an AVM is a pair $\text{F} : v$, denoting that the feature F has the value v; the value can either be atomic or complex, in the form of another AVM. In addition, certain values can be associated with variables, which serve

Motivation

Early attempts to formally describe the structure of natural languages (Chomsky, 1956) resulted in the development of formal grammars, of which context-free grammars (CFGs) are a notable example. Context-free grammars, however, have been found inadequate for this purpose, not only because some natural languages are, apparently, beyond the expressive power of CFGs (Shieber, 1985; Manaster-Ramer, 1987), but also because CFGs do not provide sufficiently succinct descriptions of the phenomena linguists are usually interested in. The main drawback of CFGs (and other phrase-structure formalisms, including early incarnations of tree-adjoining grammars (Joshi *et al.*, 1975)) in this respect is that the symbols they manipulate are 'atomic,' with no inherent structure, whereas the linguistic entities that have to be modeled by them are inherently structured. For example, words have properties such as number, gender, tense or root; phrases are categorized and subcategorized; phonemes are described as sets of features; etc.

A natural way of extending phrase-structure grammars to rectify this problem is by incorporating 'properties' of symbols into the grammar, further specifying the crude categorial information. This is achieved by replacing the atomic symbols of CFGs by 'feature structures,' which provide a natural representation for the kind of linguistic information grammars specify. In this view, the lexicon associates with each word a set of feature structures, rather than a set of atomic terminal symbols, and grammar rules are defined over feature structures, rather than over atomic nonterminal symbols. With this extension, rule application has to be amended, too, and comparing two symbols cannot be simply reduced to identity checking, as is the case in CFGs. Rather, an information comparison and combination operation, 'unification,' is used to decide whether a rule can be applied to some form. This article defines feature structures (the second section), unification (the third section) and unification grammars (the fourth section) from a computational point of view. For a more linguistically oriented discussion of unification and default unification, refer to Bouma (**Unification, Classical and Default**).

The move from CFGs to unification grammars provides an additional dimension for linguistic generalizations. It facilitates the expression of linguistic constraints by means of a single rule, instead of a collection of 'similar' rules. More significantly, it also results in a dramatic increase in expressive power: the set of languages that can be defined by unification grammars is much larger than the set of context-free languages; in terms of the Chomsky (1956) hierarchy of languages, this is the set of recursively enumerable (type-0) languages. Consequently, computational processing of unification grammars is significantly less efficient than processing with CFGs. Some of these issues are discussed in the last section.

Feature Structures

Attribute-Value Matrices

Feature structures are graphically represented using a notation known as attribute-value matrices (AVMs). Such matrices list, within square brackets, a set of features, along with their values. Each 'row' in an AVM is a pair $F : v$, denoting that the feature F has the value v; the value can either be atomic or complex, in the form of another AVM. In addition, certain values can be associated with variables, which serve

as pointers to the values. Variables are denoted by numeric indices enclosed in a square. These notions are further elaborated in this section.

An AVM is a syntactic object, which can be either atomic or a complex. Each AVM is associated with a variable, the idea being that two occurrences of the same variable denote one and the same value. An atomic feature structure is a variable, associated with an 'atom,' drawn from a fixed set ATOMS; these will usually be nonstructured linguistic notions such as singular, plural or accusative. A complex feature structure is a variable, associated with a finite, possibly empty set of pairs, where each pair consists of a feature and a value. Features are drawn from a fixed (per grammar), predefined set FEATS; values are, recursively, AVMs themselves. Thus, FEATS and ATOMS, as well as the (infinite) set of variables, are parameters for the collection of AVMs, and are referred to as the 'signature' over which feature structures are defined.

(1) In the following AVM, the set of variables includes $\boxed{3}$,$\boxed{5}$,$\boxed{6}$ and $\boxed{8}$. FEATS = {AGR, NUM, PERS} and ATOMS = {*pl, third*}.

$$\boxed{3}\begin{bmatrix}\text{AGR}: & \boxed{5}\begin{bmatrix}\text{NUM}: & \boxed{6}pl\\ \text{PERS}: & \boxed{8}third\end{bmatrix}\end{bmatrix}$$

Meta-variables F, G, H are used to range over FEATS and *A, B, C* to range over feature structures. If

$$A = \boxed{i_0}\begin{bmatrix}F_1: & \boxed{i_1}A_1\\ \vdots & \vdots\\ F_n: & \boxed{i_n}A_n\end{bmatrix}$$

is a complex feature structure then the 'domain' of A is $dom(A) = \{F_i \mid 1 \leq i \leq n\}$. When A is atomic, $dom(A)$ is undefined. A special case of a feature structure is the empty one, denoted [ ], whose domain is the empty set of features. Note that, $|dom(A)| = n$. That is, for every $1 \leq i, j \leq n$ such that $i \neq j$, $F_i \neq F_j$. This uniqueness of value assignment by A to each F_i (known also as the 'functional' character of feature structures) is very essential. In particular, the order of the 'rows' in an AVM is not important, and any permutation of this order will result in an identical AVM. The 'value' of a feature F_i in A is $val(A, F_i) = A_i$. If $F \notin dom(A)$ then $val(A, F)$ is undefined.

Since variables are used to denote value sharing, there is not much sense in associating the same variable with two different values. Therefore, an AVM is well formed if for every variable occurring in it, all its occurrences are associated with the same value.

(2) The following AVM, A, is well formed since both occurrences of $\boxed{1}$ are associated with the same value, *a*. B is not well formed due to the two incompatible assignments of $\boxed{1}$; C is not well formed because the values associated with $\boxed{1}$ are different:

$$A = \boxed{3}\begin{bmatrix}\text{F}: & \boxed{1}a\\ \text{G}: & \boxed{2}\begin{bmatrix}\text{H}: & \boxed{1}a\end{bmatrix}\end{bmatrix},\ B = \boxed{4}\begin{bmatrix}\text{F}: & \boxed{1}\begin{bmatrix}\text{H}: & \boxed{2}a\end{bmatrix}\\ \text{G}: & \boxed{1}b\end{bmatrix},$$

$$C = \boxed{3}\begin{bmatrix}\text{F}: & \boxed{1}\begin{bmatrix}\text{H}: & \boxed{4}a\end{bmatrix}\\ \text{G}: & \boxed{1}\begin{bmatrix}\text{K}: & \boxed{5}b\end{bmatrix}\end{bmatrix}$$

In the sequel, all AVMs are assumed to be well formed. Furthermore, since multiple occurrences of the same variable are always associated with the same values, only one instance of this value is explicated, leaving the other occurrences of the same variable unspecified. As another convention, whenever a variable is associated with the empty AVM, the AVM itself is omitted and only the variable is specified. Finally, if a variable occurs only once in an AVM, it is usually not depicted (as it carries no additional information).

(3) Consider the following feature structure, A:

$$\begin{bmatrix}\text{F}: & \boxed{3}a\\ \text{G}: & \boxed{4}\begin{bmatrix}\text{H}: & \boxed{3}a\end{bmatrix}\\ \text{H}: & \boxed{2}[\,]\end{bmatrix}$$

Notice that it is well formed, since the only variable occurring more than once ($\boxed{3}$) is associated with the same value (*a*) in both its occurrences. Therefore, one occurrence of the value can be left explicit, yielding:

$$\begin{bmatrix}\text{F}: & \boxed{3}\\ \text{G}: & \boxed{4}\begin{bmatrix}\text{H}: & \boxed{3}a\end{bmatrix}\\ \text{H}: & \boxed{2}[\,]\end{bmatrix}$$

Next, the tag $\boxed{2}$ is associated with the empty feature structure, which can be omitted:

$$\begin{bmatrix}\text{F}: & \boxed{3}\\ \text{G}: & \boxed{4}\begin{bmatrix}\text{H}: & \boxed{3}a\end{bmatrix}\\ \text{H}: & \boxed{2}[\,]\end{bmatrix}$$

Finally, the tag $\boxed{4}$ occurs only once, so it can be omitted:

$$\begin{bmatrix} \text{F}: & \boxed{3} \\ \text{G}: & \begin{bmatrix} \text{H}: & \boxed{3}a \end{bmatrix} \\ \text{H}: & \boxed{2} \end{bmatrix}$$

A 'path' is a (possibly empty) sequence of features that can be used to pick a value in a feature structure. Angular brackets '$\langle \ldots \rangle$' are used to depict paths explicitly. For example, in the AVM A of example (3), the single feature $\langle$F$\rangle$ constitutes a path; and so does the sequence $\langle$G,H$\rangle$, since $\langle$G$\rangle$ can be used to pick the value $\begin{bmatrix} \text{H}: & \boxed{3}a \end{bmatrix}$ (because $val(A, \text{G}) = \begin{bmatrix} \text{H}: & \boxed{3}a \end{bmatrix}$). In more complex AVMs, with deeper levels of embedding, longer paths can be used recursively to reach more deeply nested features. The set of all the paths of A is denoted $\Pi(A)$.

The notion of values is extended from features to paths: $val(A, \pi)$ is the value obtained by following the path π in A; this value (if defined) is again a feature structure. If A_i is the value of some path π in A then A_i is said to be a *sub-AVM* of A. The empty path is denoted ε, and $val(A, \varepsilon) = A$ for every feature structure A.

(4) Let $A = \begin{bmatrix} \text{AGR}: & \begin{bmatrix} \text{NUM}: & pl \\ \text{PERS}: & third \end{bmatrix} \end{bmatrix}$

Then $dom(A) = \{\text{AGR}\}$, and

$$val(\text{A}, \text{AGR}) = \begin{bmatrix} \text{NUM}: & pl \\ \text{PERS}: & third \end{bmatrix}$$

The paths of A are $\prod(A) = \{\varepsilon, \langle\text{AGR}\rangle, \langle\text{AGR, NUM}\rangle, \langle\text{AGR, PERS}\rangle\}$. The values of these paths are: $val(A, \varepsilon) = A$, $val(A, \langle\text{AGR,NUM}\rangle) = pl$, $val(A, \langle\text{AGR,PERS}\rangle) = third$. Since there is no path $\langle\text{NUM,AGR}\rangle$ in A, $val(A, \langle\text{NUM,AGR}\rangle)$ is undefined.

When two paths in an AVM lead to sub-AVMs that are associated with the same variable, the paths are said to be reentrant; reentrancy in some feature structure A is denoted by the symbol '$\underset{\sim}{A}$.' For example, in the feature structure

$$A_3 = \begin{bmatrix} \text{SUBJ}: & \begin{bmatrix} \text{AGR}: & \boxed{1}\begin{bmatrix} \text{NUM}: & plural \end{bmatrix} \end{bmatrix} \\ \text{OBJ}: & \begin{bmatrix} \text{AGR}: & \boxed{1} \end{bmatrix} \end{bmatrix}$$

the paths $\langle$SUBJ, AGR$\rangle$ and $\langle$OBJ, AGR$\rangle$ are reentrant, that is, $\langle$SUBJ, AGR$\rangle$ $\underset{\sim}{A}$ $\langle$OBJ, AGR$\rangle$. The distinction between 'being the same entity,' or being identical, and being 'similar but distinct' entities, is referred to in the literature as the distinction between 'token identity' and 'type identity,' respectively.

(5) Consider the following feature structure:

$$A = \begin{bmatrix} \text{SUBJ}: & \begin{bmatrix} \text{AGR}: & \begin{bmatrix} \text{NUM}: & sg \\ \text{PERS}: & third \end{bmatrix} \end{bmatrix} \\ \text{OBJ}: & \begin{bmatrix} \text{AGR}: & \begin{bmatrix} \text{NUM}: & sg \\ \text{PERS}: & third \end{bmatrix} \end{bmatrix} \end{bmatrix}$$

In A, the features SUBJ and OBJ have equal, but not token-identical, values. In contrast, consider the following AVM:

$$B = \begin{bmatrix} \text{SUBJ}: & \boxed{4}\begin{bmatrix} \text{AGR}: & \begin{bmatrix} \text{NUM}: & sg \\ \text{PERS}: & third \end{bmatrix} \end{bmatrix} \\ \text{OBJ}: & \boxed{4} \end{bmatrix}$$

In B, the values of SUBJ and OBJ are not only type-identical, they are also token-identical; in effect, there is only one and the same value shared by both features in B. The two features simply 'point' to this one value, in much the same way as pointers in programming languages might be set to refer to the same location in memory.

An important consequence of token identity is the following: if the value of one of two features having a shared value is modified, this modification is immediately 'sensed' by the other feature and its value also changes to the same new value. This is demonstrated in example (6).

(6) Consider again the following feature structures:

$$A = \begin{bmatrix} \text{SUBJ}: & \begin{bmatrix} \text{AGR}: & \begin{bmatrix} \text{NUM}: & sg \\ \text{PERS}: & third \end{bmatrix} \end{bmatrix} \\ \text{OBJ}: & \begin{bmatrix} \text{AGR}: & \begin{bmatrix} \text{NUM}: & sg \\ \text{PERS}: & third \end{bmatrix} \end{bmatrix} \end{bmatrix}$$

$$B = \begin{bmatrix} \text{SUBJ}: & \boxed{4}\begin{bmatrix} \text{AGR}: & \begin{bmatrix} \text{NUM}: & sg \\ \text{PERS}: & third \end{bmatrix} \end{bmatrix} \\ \text{OBJ}: & \boxed{4} \end{bmatrix}$$

Observe that $val(A, \text{SUBJ}) = val(A, \text{OBJ})$ and $val(B, \text{SUBJ}) = val(B, \text{OBJ})$. However, while $val(B, \text{SUBJ})$ and

val(*B*, OBJ) are token-identical, this is not the case for *A: val*(*A*, SUBJ) and *val*(*A*, OBJ) are only type-identical. Suppose that by some action (as shown below), a feature CASE with the value nom is added to the value of SUBJ in both *A* and *B*. The outcome of such an operation has different effects on the two feature structures. In *A*, it will result in:

$$A' = \begin{bmatrix} \text{SUBJ}: & \begin{bmatrix} \text{AGR}: & \begin{bmatrix} \text{NUM}: & sg \\ \text{PERS}: & third \end{bmatrix} \\ \text{CASE}: & nom \end{bmatrix} \\ \text{OBJ}: & \begin{bmatrix} \text{AGR}: & \begin{bmatrix} \text{NUM}: & pl \\ \text{PERS}: & third \end{bmatrix} \end{bmatrix} \end{bmatrix}$$

In particular, note that *val*(*A*', SUBJ) $\neq$ *val*(*A*', OBJ). However, in *B* the effect would be:

$$B' = \begin{bmatrix} \text{SUBJ}: & \boxed{4} \begin{bmatrix} \text{AGR}: & \begin{bmatrix} \text{NUM}: & sg \\ \text{PERS}: & third \end{bmatrix} \\ \text{CASE}: & nom \end{bmatrix} \\ \text{OBJ}: & \boxed{4} \end{bmatrix}$$

Here, *val*(*B*', SUBJ) and *val*(*B*', OBJ) are token-identical, implying *val*(*B*', SUBJ) = *val*(*B*', OBJ). Since the values are token identical, the operation has affect over the two reentrant features.

Unification-based theories of language make extensive use of reentrancy to encode grammatical relations. In fact, it is instructive to think of re-entrancies as the unification equivalent of 'movement' in generative linguistics. Feature structures can be arbitrarily complex, and by sharing a single value between two distinct paths, a theory can express the notion of this value being 'moved' from the end of one path to the end of another. However, there is no notion of direction for such movement: the shared value is the common value of both paths, symmetrically.

A special case of reentrancy is 'cyclicity': an AVM can contain a path whose value is the AVM itself. In other words, an AVM can be reentrant with a substructure of itself:

$$A = \begin{bmatrix} \text{F}: & \boxed{2} \begin{bmatrix} \text{G}: & a \\ \text{H}: & \boxed{2} \end{bmatrix} \end{bmatrix}$$

Notice that, in the face of cycles there is no way to fully depict (in some finite way) an AVM, unless the convention of omitting multiple occurrences of shared values is adopted (as above).

Feature Graphs

AVMs are the common representation of feature structures in the linguistic literature. To model AVMs computationally, a graph representation, called 'feature graphs,' is used. Feature graphs are defined over a signature consisting of fixed, nonempty, finite, disjoint sets FEATS of features and ATOMS of atoms, as before.

A feature graph $A = \langle Q_A, \bar{q}_A, \delta_A, \theta_A \rangle$ is a finite, directed, connected, labeled graph consisting of a finite, nonempty set of nodes Q_A (such that $Q_A \cap \text{FEATS} = Q_A \cap \text{ATOMS} = \emptyset$), a root $\bar{q}_A \in Q_A$, a partial function $\delta_A : Q_A \times \text{FEATS} \rightarrow Q_A$ specifying the arcs such that every node $q \in Q_A$ is accessible from $\bar{q}_A$, and a partial function, marking some of the sinks: $\theta_A : Q_S \rightarrow \text{ATOMS}$, where $Q_S = \{q \in Q_A \mid \delta_A\ (q, \text{F})$ is undefined for every $\text{F}\}$. The arcs of a feature graph are thus labeled by features. The root is a designated node from which all other nodes are accessible (through δ); note that nothing prevents the root from having incoming arcs. Sink nodes (nodes with no outgoing edges) can be marked by an atom, but can also be unmarked.

How are the graphs defined above related to the AVMs presented in the previous section? Informally, atomic AVMs are modeled by single nodes, labeled by the atom, with no outgoing arcs. Empty AVMs are modeled by a graph having just one node, bearing no label and having no outgoing features. Complex AVMs denote graphs whose nodes, including the root, may have outgoing arcs, where the arcs' labels correspond to features. The following example depicts both the AVM and the graph representations of feature graphs, where the root is depicted as a gray-colored node.

(7) Consider the AVM A of example (4), repeated here for convenience. A is modeled by the following graph:

$$\begin{bmatrix} \text{AGR}: & \begin{bmatrix} \text{NUM}: & pl \\ \text{PERS}: & third \end{bmatrix} \end{bmatrix}$$

The graph displayed above is $\langle Q, \bar{q}, \delta, \theta \rangle$, *where* $Q = \{q_0, q_1, q_2, q_3\}$, $\bar{q} = q_0$, $\delta(q_0, \text{AGR}) = q_1$, $\delta(q_1, \text{NUM}) = q_2$, $\delta(q_1, \text{PERS}) = q_3$, $Q_S = \{q_2, q_3\}$, $\theta(q_2) = pl$, $\theta\ (q_3) = third$.

In the following graph, the values of the features NUM and PERS are unspecified. This is reflected in the graph by having the leaves q_2 and q_3 bear no marking; in other words, the marking function θ is undefined for the two sinks in its domain.

$$\begin{bmatrix} \text{AGR}: & \begin{bmatrix} \text{NUM}: & [\,] \\ \text{PERS}: & [\,] \end{bmatrix} \end{bmatrix}$$

The graph displayed above is $\langle Q, \bar{q}, \delta, \theta \rangle$, *where* $Q = \{q_0, q_1, q_2, q_3\}$, $\bar{q} = q_0$, $\delta(q_0, \text{AGR}) = q_1$, $\delta(q_1, \text{NUM}) = q_2$, $\delta(q_1, \text{PERS}) = q_3$, $Q_S = \{q_2, q_3\}$, and θ is undefined for its entire domain.

Feature Structures

Since feature graphs are simply a special case of directed, labeled graphs, the well-defined notion of graph 'isomorphism' can be adapted to feature graphs. Informally, two graphs are isomorphic when they have the same structure; the identities of their nodes may differ without affecting the structure. In the case of feature graphs, the labels of sink nodes are also required to be identical in order for two graphs to be considered isomorphic.

Two feature graphs $A = \langle Q_A, \bar{q}_A, \delta_A, \theta_A \rangle$ and $B = \langle Q_B, \bar{q}_B, \delta_B, \theta_B \rangle$ are isomorphic, denoted $A \sim B$, iff there exists a one-to-one mapping $i : Q_A \rightarrow Q_B$, called an isomorphism, such that:

- $i(\bar{q}_A) = \bar{q}_B$;
- for all $q_1, q_2 \in Q_A$ and $f \in \text{FEATS}$, $\delta_A\ (q_1, f) = q_2$ iff $\delta_B\ (i(q_1), f) = i(q_2)$; and
- for all $q \in Q_A$, $\theta_A(q) = \theta_B(i(q))$ (either both are undefined, or both are defined and equal).

Given a feature graph A, a feature structure $\hat{A}$ is the equivalence class of all the feature graphs that are isomorphic to A: $[A]\sim$.

The definition of feature structures as equivalence classes of isomorphic feature graphs calls for a natural lifting of some properties of feature graphs to feature structures. This can be naturally achieved since if $\hat{A}$ is a feature structure and $A \in \hat{A}$, $B \in \hat{A}$ are two isomorphic feature graphs in $\hat{A}$, then

- $\Pi(A) = \Pi(B)$
- for each $\pi \in \Pi(A)$, $val(A, \pi) \sim val(B, \pi)$
- for each $\pi_1, \pi_2 \in \Pi(A)$, $\pi_1 \underset{A}{\leftrightsquigarrow} \pi_2$ iff $\pi_1 \underset{B}{\leftrightsquigarrow} \pi_2$ (and, therefore, A is reentrant/cyclic iff B is reentrant/cyclic).

This facilitates a view of feature structures as graphs, abstracting over the identities of the nodes. Such concepts are sometimes known as 'abstract feature structures' in the literature.

The terms 'AVM' and 'feature structure' are used interchangeably in the rest of this article. Feature structures are reminiscent of first-order terms (FOTs), familiar from logic and in particular logic programming. There are, however, significant differences. First and foremost, FOTs are essentially trees, with possibly shared leaves, whereas feature structures allow reentrancies to occur in every level of the structure. Feature structures can be cyclic, in contrast to (ordinary) FOTs. FOTs use positional encoding of argument structures, with no features. Finally, two FOTs are unifiable only if they have the same functor and the same arity, while two feature structures might be unifiable even if they have different numbers of features, see 'Subsumption and Unification.' The relationships between feature structures and first-order terms is investigated by Penn (2000). A mathematical characterization of feature structures and a discussion of their properties can be found in, e.g., Johnson (1988) or Shieber (1992).

Typed Feature Structures

An additional dimension through which linguistic generalizations can be expressed is obtained by introducing 'typing' to feature structures. The motivation for typing stems from the observation that certain features are more appropriate to some feature structures than to others. For example, consider the two AVMs below:

$$A = \begin{bmatrix} \text{CAT}: & v \\ \text{SUBCAT}: & elist \\ \text{AGR}: & \begin{bmatrix} \text{NUM}: & pl \\ \text{PERS}: & 3rd \end{bmatrix} \end{bmatrix}, \qquad B = \begin{bmatrix} \text{NUM}: & pl \\ \text{PERS}: & 3rd \end{bmatrix}$$

In neither of these structures is the feature GENDER defined, but this feature is certainly more appropriate for B than for the top level of A (although adding it to the AVM that is the value of AGR in A **is** natural). Informally, one would like to claim that the feature GENDER is appropriate for feature structures that model agreement properties (such as B or $val(A, \text{AGR})$ above), but not for feature structures that model signs (such as A). This is not a mathematical claim; it is a claim concerning the intended interpretation of feature structures. To formalize this notion, feature structures are classified, and the names of classes are called types (sometimes referred to as 'sorts'). When each feature structure is associated with a certain type, it becomes possible to define what features are appropriate for a given type, t; these features will be appropriate for every feature structure of type t. For example, the feature structure A above can be assigned the type *sign*, as it represents a linguistic sign; whereas the feature structure B can be assigned the type *agr*, to indicate the fact that it is a collection of agreement features. Now the feature GENDER could be defined as appropriate for the type *agr* but not for the type *sign*.

The move to typed feature structures necessitates an extension of the signature over which feature structures are defined: in addition to the set FEATS of features, a (finite) set TYPES of types is required. Incidentally, the introduction of types renders the set of atoms, ATOMS, redundant, as atoms can be represented using types.

Once types and feature appropriateness are introduced, it is possible to extend their use: it should be clear that for different features, different types of values are appropriate. For example, the feature AGR must be restricted to bear only values of the type *agr*; whereas for the feature GENDER, for example, such values must not be appropriate. Furthermore, a typed system can include a mechanism for **forcing** the occurrence of a certain feature in a TFS, not just for **allowing** it.

As mentioned above, types can be viewed as naming classes of feature structures; a natural outcome of this view is the imposing of 'order' on types, to reflect the natural set inclusion order on sets of feature structures (of those types). It is possible to extend appropriateness to respect this order, such that if a feature is appropriate for a type, it is also appropriate for all its subtypes.

A typed system allows the grammar designer to impose restrictions on feature structures that reflect real-world or linguistic constraints. It enables better generalizations to be stipulated as it gives the grammar writer an additional dimension in which to state such generalizations: linguistic constraints can be defined in terms of types rather than in terms of features. For example, most of the 'rules' of the linguistic theory HPSG are stipulated as constraints on types: if a feature structure is of a certain type, then certain constraints must hold.

While the use of types in linguistic theories is primarily motivated by linguistic considerations, there are several additional, mathematical and computational, advantages to their use. The incorporation of types into programming languages has become the standard. Types provide means for several compile-time and run-time errors to be detected. They allow – in particular when combined with appropriateness – for several optimizations in implementations of feature structure-based formalisms, resulting in more efficient processing. Finally, as in programming languages, the use of types aids in grammar organization and modularization. For simplicity, however, the rest of this article discusses untyped feature structures only.

Linguistic motivation for the use of typed AVMs is first given by Aït-Kaci (1984), who also provides mathematical and computational motivation for using types. This work influenced the development of the linguistic theory Head-Drive Phrase-Structure grammars (HPSG) (Pollard and Sag, 1987, 1994), which remains the main theory that employs TFSs. TFSs are directly defined also by Moshier (1988), and a view of TFSs as a generalization of first-order terms is presented in Carpenter (1991). A logical formulation of TFSs, starting in the basic notions and ending in a complete characterization of TFS-based grammars and their languages, is given by Carpenter (1992). Wintner and Sarkar (2002) show how typing can be beneficial even for systems that employ untyped feature structures.

Subsumption and Unification

Subsumption

Feature structures are used to represent linguistic information, and the amount of information stored within different feature structures can be compared, thus inducing a natural (partial) order on the structures. This relation is called 'subsumption' and is denoted '$\sqsubseteq$.' If A and B are feature structures over the same signature, then A *subsumes* B ($A \sqsubseteq B$; also, A is more general than B, and B is *subsumed by*, or is more specific than, A) if the following conditions hold:

1. if A is an atomic AVM then B is an atomic AVM with the same atom;
2. for every $\text{F} \in \text{FEATS}$, if $\text{F} \in dom(A)$ then $\text{F} \in dom(B)$, and $val(A, \text{F})$ subsumes $val(B, \text{F})$; and
3. if two paths are reentrant in A, they are also reentrant in B: if $\pi_1 \underset{\leftrightsquigarrow}{A} \pi_2$ then $\pi_1 \underset{\leftrightsquigarrow}{B} \pi_2$.

The second condition of the definition is recursive; the recursion ends when an empty value or an atomic value is encountered. Note, the direction of the ordering: greater structures are more specific, i.e., contain more information. This extra information can be manifested as additional features having a defined value, or more specific values for an existing feature, or more reentrancies.

(8) The empty feature structure, [ ], is the most general feature structure, subsuming all others, including atoms (as it encodes no information at all). Since it contains no features (and, hence, no paths), it satisfies the conditions of the subsumption definition vacuously. In particular, it subsumes a feature structure that determines the value of the NUM feature to be *sg*:

$$[\,] \sqsubseteq \begin{bmatrix} \text{NUM}: & sg \end{bmatrix}$$

In the same way,

$$\begin{bmatrix} \text{NUM}: & [\,] \end{bmatrix} \sqsubseteq \begin{bmatrix} \text{NUM}: & sg \end{bmatrix}$$

since the empty feature structure subsumes the atomic feature structure *sg*.

Adding more information, say, about the PERSON feature, results in a more specific feature structure:

$$\begin{bmatrix} \text{NUM}: & sg \end{bmatrix} \sqsubseteq \begin{bmatrix} \text{NUM}: & sg \\ \text{PERS}: & third \end{bmatrix}$$

Another way to add information is through reentrancies:

$$\begin{bmatrix} \text{NUM1}: & sg \\ \text{NUM2}: & sg \end{bmatrix} \sqsubseteq \begin{bmatrix} \text{NUM1}: & \boxed{1}sg \\ \text{NUM2}: & \boxed{1} \end{bmatrix}$$

Subsumption is a partial relation: not every pair of feature structures is comparable. For example, it is impossible to say which of the following feature structures encodes more information:

$$\begin{bmatrix} \text{NUM}: & sg \end{bmatrix} \begin{matrix} \not\sqsubseteq \\ \not\sqsupseteq \end{matrix} \begin{bmatrix} \text{NUM}: & pl \end{bmatrix}$$

A different case of incomparability is caused by the existence of different features in the two structures. Since each of the AVMs in the following example has a feature that is not defined in the other, none is more specific than the other:

$$\begin{bmatrix} \text{NUM}: & sg \end{bmatrix} \begin{matrix} \not\sqsubseteq \\ \not\sqsupseteq \end{matrix} \begin{bmatrix} \text{PERS}: & third \end{bmatrix}$$

While subsumption informally encodes an order of information content among AVMs, sometimes the informal notion can be misleading. For example, the following two AVMs informally encode the same information, pertaining to the agreement features of some entity; formally, however, neither subsumes the other.

$$\begin{bmatrix} \text{NUM}: & sg \\ \text{PERS}: & third \end{bmatrix} \begin{matrix} \not\sqsubseteq \\ \not\sqsupseteq \end{matrix} \begin{bmatrix} \text{AGR}: & \begin{bmatrix} \text{NUM}: & sg \\ \text{PERS}: & third \end{bmatrix} \end{bmatrix}$$

Subsumption has the following properties:

- Least element: the empty feature structure subsumes every feature structure: for every feature structure A, $[\,] \sqsubseteq A$.
- Reflexivity: for every feature structure A, $A \sqsubseteq A$.
- Transitivity: If $A \sqsubseteq B$ and $B \sqsubseteq C$ than $A \sqsubseteq C$.
- Antisymmetry: If $A \sqsubseteq B$ and $B \sqsubseteq A$ then $A = B$.

Since subsumption is a partial, reflexive, transitive, and antisymmetric relation, it is a partial order.

It is possible to define subsumption directly in terms of feature graphs. Let $A_1 = \langle Q_1, \bar{q}_1, \delta_1, \theta_1 \rangle$ and $A_2 = \langle Q_2, \bar{q}_2, \delta_2, \theta_2 \rangle$ be two feature graphs. A_1 subsumes A_2 (denoted by $A_1 \sqsubseteq A_2$) iff there exists a total function $h : Q_1 \rightarrow Q_2$, called a subsumption morphism, such that:

- $h(\bar{q}1) = \bar{q}_2$
- for every $q \in Q_1$ and for every F such that $\delta_1(q, \text{F})$ is defined, $h(\delta_1(q, \text{F})) = \delta_2(h(q), \text{F})$
- for every $q \in Q_1$, if $\theta_1(q)$ is defined then $\theta_1(q) = \theta_2(h(q))$

The morphism h associates with every node in Q_1 a node in Q_2; if an arc labeled F connects q with q', then such an arc connects $h(q)$ with $h(q')$. In other words, δ and h 'commute.' In addition, if a node $q \in Q_1$ is marked by an atom, then its image $h(q)$ must be marked by the same atom (recall that only sinks can be thus marked). Note that, if a sink in Q_1 is **not** marked, there is no constraint on its image (in particular, it can be a nonsink).

Unification

Motivated by the view of feature structures as representing information, it is useful to have an operation that combines, whenever possible, the information that is encoded in two feature structures. The unification operation, denoted '$\sqcup$,' is defined over pairs of feature structures, and yields the most general feature structure that is more specific than both operands, if one exists: $A = B \sqcup C$ if and only if A is the most general feature structure such that $B \sqsubseteq A$ and $C \sqsubseteq A$. If such a structure exists, the unification succeeds, and the two arguments are said to be unifiable (or consistent). If none exists, the unification fails, and the operands are said to be inconsistent (denoted $B \sqcup C = \top$). In terms of the subsumption ordering, nonfailing unification returns the least upper bound (*lub*) of its arguments. Example (9) sheds light on different aspects of the unification operation.

(9) Unification combines consistent information:

$$\begin{bmatrix} \text{NUM}: & sg \end{bmatrix} \sqcup \begin{bmatrix} \text{PERS}: & third \end{bmatrix} = \begin{bmatrix} \text{NUM}: & sg \\ \text{PERS}: & third \end{bmatrix}$$

Different atoms are inconsistent:

$$\begin{bmatrix} \text{NUM}: & sg \end{bmatrix} \sqcup \begin{bmatrix} \text{NUM}: & pl \end{bmatrix} = \top$$

Atoms and nonatoms are inconsistent:

$$\begin{bmatrix} \text{NUM}: & sg \end{bmatrix} \sqcup pl = \top$$

Unification is absorbing:

$$\begin{bmatrix} \text{NUM}: & sg \end{bmatrix} \sqcup \begin{bmatrix} \text{NUM}: & sg \\ \text{PERS}: & third \end{bmatrix} = \begin{bmatrix} \text{NUM}: & sg \\ \text{PERS}: & third \end{bmatrix}$$

Empty feature structures are identity elements:

$$[] \sqcup \begin{bmatrix} \text{AGR}: & \begin{bmatrix} \text{NUM}: & sg \end{bmatrix} \end{bmatrix} = \begin{bmatrix} \text{AGR}: & \begin{bmatrix} \text{NUM}: & sg \end{bmatrix} \end{bmatrix}$$

Reentrancy causes two consistent values to coincide:

$$\begin{bmatrix} \text{F}: & \begin{bmatrix} \text{NUM}: & sg \\ \text{PERS}: & third \end{bmatrix} \\ \text{G}: & \end{bmatrix} \sqcup \begin{bmatrix} \text{F}: & \boxed{1} \\ \text{G}: & \boxed{1} \end{bmatrix} \quad \begin{bmatrix} \text{F}: & \boxed{1} \begin{bmatrix} \text{NUM}: & sg \\ \text{PERS}: & third \end{bmatrix} \\ \text{G}: & \boxed{1} \end{bmatrix}$$

Unification acts differently depending on whether the values are equal:

$$\begin{bmatrix} \text{F}: & \begin{bmatrix} \text{NUM}: & sg \end{bmatrix} \\ \text{G}: & \begin{bmatrix} \text{NUM}: & sg \end{bmatrix} \end{bmatrix} \sqcup \begin{bmatrix} \text{F}: & \begin{bmatrix} \text{PERS}: & third \end{bmatrix} \end{bmatrix} = \begin{bmatrix} \text{F}: & \begin{bmatrix} \text{NUM}: & sg \\ \text{PERS}: & third \end{bmatrix} \\ \text{G}: & \begin{bmatrix} \text{NUM}: & sg \end{bmatrix} \end{bmatrix}$$

. . . or identical:

$$\begin{bmatrix} \text{F}: & \boxed{1} \begin{bmatrix} \text{NUM}: & sg \end{bmatrix} \\ \text{G}: & \boxed{1} \end{bmatrix} \sqcup \begin{bmatrix} \text{F}: & \begin{bmatrix} \text{PERS}: & third \end{bmatrix} \end{bmatrix} = \begin{bmatrix} \text{F}: & \boxed{1} \begin{bmatrix} \text{NUM}: & sg \\ \text{PERS}: & third \end{bmatrix} \\ \text{G}: & \boxed{1} \end{bmatrix}$$

One of the properties of unification is that it binds variables together. When two feature structures are unified, and each of them is associated with some variable, then the two variables are said to be bound to each other, which means that they both share one and the same value (the result of the unification). For all practical purposes, this is equivalent to there being only a single variable. However, the scope of the variables must be taken into account: all other occurrences of the same variables in this scope are effected. As an example, consider the following two feature structures A and B:

$$A = \begin{bmatrix} \text{F}: & \boxed{1} \begin{bmatrix} \text{NUM}: & sg \end{bmatrix} \end{bmatrix} \qquad B = \begin{bmatrix} \text{F}: & \boxed{2} \begin{bmatrix} \text{PERS}: & third \end{bmatrix} \end{bmatrix}$$

When unifying A and B, the result obtained is:

$$A \sqcup B = \begin{bmatrix} \text{F}: & \boxed{1}\boxed{2} \begin{bmatrix} \text{NUM}: & sg \\ \text{PERS}: & third \end{bmatrix} \end{bmatrix}$$

Of course, since the variables $\boxed{1}$ and $\boxed{2}$ occur nowhere else, they can be simply omitted and the result is equal to:

$$A \sqcup B = \begin{bmatrix} \text{F}: & \begin{bmatrix} \text{NUM}: & sg \\ \text{PERS}: & third \end{bmatrix} \end{bmatrix}$$

However, had either $\boxed{1}$ or occurred elsewhere (for example, as the value of some feature G in A), their values would have been modified as a result of the unification. Consider the following example:

$$\begin{bmatrix} \text{F}: & \boxed{1} \begin{bmatrix} \text{NUM}: sg \end{bmatrix} \\ \text{G}: & \boxed{1} \end{bmatrix} \sqcup \begin{bmatrix} \text{F}: & \boxed{2} \begin{bmatrix} \text{PERS}: third \end{bmatrix} \end{bmatrix} = \begin{bmatrix} \text{F}: & \boxed{3} \begin{bmatrix} \text{NUM}: sg \\ \text{PERS}: third \end{bmatrix} \\ \text{G}: & \boxed{3} \end{bmatrix}$$

The (recursive) unification of the values of the feature F in both operands causes the variables $\boxed{1}$ and $\boxed{2}$ to be bound to each other. The AVMs these variables are associated with are unified, yielding the following AVM:

$$\begin{bmatrix} \text{NUM}: & sg \\ \text{PERS}: & third \end{bmatrix}$$

Then, a fresh variable can be associated with the above AVM in the result.

Properties of unification include:

- Idempotency: $A \sqcup A = A$
- Commutativity: $A \sqcup B = B \sqcup A$
- Associativity: $A \sqcup (B \sqcup C) = (A \sqcup B) \sqcup C$
- Absorption: If $A \sqsubseteq B$ then $A \sqcup B = B$
- Monotonicity: If $A \sqsubseteq B$ then for every C, $A \sqcup C \sqsubseteq B \sqcup C$ (if both exist).

The unification operation was originally defined for first-order terms by Robinson (1965). A variety of algorithms for term unification have since been presented, among which the most popular is that of Martelli and Montanari (1982), extended to cyclic terms by Jaffar (1984). The origin of graph unification can be attributed to Kay (1985), while the general unification algorithms were adapted for feature structures by Aït-Kaci (1984) and Moshier (1988). There is an important difference between the FOT unification and feature structure unification: an FOT is said to be 'ground' if no further unifications can change its value. There is no real equivalent to the concept of groundness for nonatomic feature structures, since unifications can **always** add new features to a structure (unless it is atomic). Another important

difference between FOTs and feature structures has to do with the result of the unification operation. For FOTs, unification results in a substitution, which when applied to both unificands, yields the same FOT. In feature structures, however, unification returns a new feature structure – as if the substitution has already been applied to one of the unificands. In fact, there is no clear analog to the notion of substitution in the domain of feature structures.

Unification Grammars

AVMs were introduced above as a means of extending atomic symbols (such as terminal and nonterminal symbols of a context-free grammar) with structural (linguistic) information. In the same vein, it is possible to extend AVMs to sequences thereof, called *multi-AVMs* below, thereby defining an equivalent of phrase-structure rules over feature structures. *Multi-AVMs* were used implicitly in many implementations of unification-based grammars, but their formal definition (Sikkel, 1997), as well as a discussion of their mathematical properties (Wintner and Francez, 1995; Wintner, 1997), was done much later.

Multi-AVMs can be viewed as sequences of AVMs, with the important observation that some substructures can be shared among two or more AVMs. In other words, the scope of variables is extended from a single AVM to a *multi-AVM*: the same variable can be associated with two substructures of different AVMs. An immediate consequence is that if some substructure of an element on a *multi-AVM* (that is, a substructure of some AVM in it) is modified, this modification might effect other AVMs in the same 'sequence.' The *length* of a *multi-AVM* is the number of its elements. Meta-variables σ, ρ range over *multi-AVMs*.

(10) Following is a *multi-AVM* of length 3:

$$\begin{bmatrix} \text{CAT}: & np \\ \text{AGR}: & \boxed{1} \end{bmatrix} \begin{bmatrix} \text{CAT}: & d \\ \text{AGR}: & \boxed{1} \end{bmatrix} \begin{bmatrix} \text{CAT}: & n \\ \text{AGR}: & \boxed{1} \end{bmatrix}$$

In this example, the feature CAT is used for encoding the category of a constituent. Its values, drawn from the set ATOMS, correspond to the familiar nonterminal symbols of CFGs. The feature AGR encodes a bundle of agreement features, whichever features the determiner and the noun must agree on. The (single) value of the three AGR features is shared among the determiner, the noun, and the noun phrase.

In a unification grammar, rules are expressed as *multi-AVMs*. The *multi-AVM* of example (10) can be viewed as a rule that forms noun phrases by combining a determiner with a noun, imposing agreement between the two daughters. Furthermore, the concept of derivation and, subsequently, language of unification grammars is defined in terms of *multi-AVMs*. As shown below, derivations are manipulations of *multi-AVMs*, *forms*, obtained by successively applying grammar rules.

Note the interpretation of agreement emerging from example (10). Agreement is viewed as a bundle of features that are constrained in two (or more) independent ways, which have to be mutually compatible. Thus, the object that is the value of $\boxed{1}$ in the above example is constrained independently by the '*D*-subtree' and the '*N*-subtree,' and the rule imposes identical resulting values. This view should be contrasted with another, more 'directional,' view of agreement, according to which there is one phrase that determines the value of the bundle of features in question, while a second phrase accommodates these values. The undirectional view of agreement is a typical view of unification-based grammar formalisms, which have a constraint satisfaction view in general, in which undirectionality is inherent. In contrast, transformation-based linguistic theories employ an essential concept of movement that is inherently directional.

The notion of subsumption can be naturally extended from AVMs to *multi-AVMs*: if σ and ρ are two *multi-AVMs* of the same length, n, then $\sigma \sqsubseteq \rho$ if the following conditions hold:

1. every element of σ subsumes the corresponding element of ρ; and
2. if two paths are reentrant in σ, they are also reentrant in ρ.

Note that the second condition refers to reentrancies that possibly relate paths originating in different elements of each *multi-AVM*.

(11) Let σ be the *multi-AVM*:

$$\begin{bmatrix} \text{F}: & \begin{bmatrix} \text{G}: & a \\ \text{H}: & \boxed{1} \end{bmatrix} \end{bmatrix} \begin{bmatrix} \text{G}: & c \end{bmatrix} \begin{bmatrix} \text{F}: & \begin{bmatrix} \text{H}: & v \\ \text{G}: & \boxed{1}d \end{bmatrix} \\ \text{H}: & a \end{bmatrix}$$

and ρ be:

$$\begin{bmatrix} \text{F}: & \begin{bmatrix} \text{G}: & a \\ \text{H}: & d \end{bmatrix} \end{bmatrix} \begin{bmatrix} \text{G}: & c \end{bmatrix} \begin{bmatrix} \text{F}: & \begin{bmatrix} \text{H}: & b \\ \text{G}: & d \end{bmatrix} \\ \text{H}: & a \end{bmatrix}$$

Then σ does not subsume ρ, but $\rho \sqsubseteq \sigma$. This is because of the reentrancy between the values $val(\sigma, 1, \langle F,H \rangle)$ and $val(\sigma,3,\langle F,G \rangle)$; This constraint does not occur in ρ, contributing to ρ's being more general (less specific).

In the same way, the notion of unification can be extended to *multi-AVMs* (of the same length): ρ is the unification of σ_1 and σ_2 (denoted $\rho = \sigma_1 \sqcup \sigma_2$) if σ_1, σ_2, and ρ are of the same length, and ρ is the most general *multi-AVM* that is more specific than both σ_1 and σ_2.

A different unification operation on *multi-AVMs*, *unification in context*, unifies an element of one *multi-AVM* with an element of the other, resulting in possible modifications to both operands. Informally, the two AVMs (associated with the head of some rule and with the selected element in some form) are unified in their respective contexts: the body of the rule and the entire form. When some variable $\boxed{1}$ in the form is unified with some variable $\boxed{2}$ in the rule, all occurrences $\boxed{1}$ of in the form and of $\boxed{2}$ in the rule are modified: they are all set to the unified value. Note, however, that while the rule can be affected by the unification operation, it is only an instance of the rule that is used for each derivation step; derivation cannot alter the grammar itself.

A unification grammar consists of a set of rules, each of which is a *multi-AVM*; a lexicon, which associates a set of AVMs with each word; and a start symbol, which is an AVM. Rules are applied successively on forms, which are themselves *multi-AVMs*, starting with the form that consists of the start symbol only. *Derivation* is a binary relation over forms. Let σ be a form and ρ a grammar rule; application of ρ to σ consists of the following steps:

- Matching the rule's head with some element of the form, the *selected element*;
- Replacing the selected element in the form with the body of the rule, producing a new form.

This process is more involved than CFG derivation due to the presence of feature structures. Matching consists of unifying the head of the rule with the selected element; the rule is only applicable to the form if the unification does not fail. Due to possible reentrancies among elements of the form or the rule, the replacement operation requires unification in context of the head of the rule and the selected element. The replacement operation inserts the modified rule body into the modified form, replacing the selected element of the form. The full derivation relation is, as usual, the reflexive-transitive closure of rule application. A form is *sentential* if it is derivable from the start symbol.

(12) Consider the form

$$\sigma = \begin{bmatrix} \text{CAT} : np \\ \text{AGR} : \boxed{1} \end{bmatrix} \begin{bmatrix} \text{CAT} : np \\ \text{AGR} : \boxed{1} \end{bmatrix}$$

and the rule

$$\rho = \begin{bmatrix} \text{CAT} : np \\ \text{AGR} : \boxed{2} \end{bmatrix} \rightarrow \begin{bmatrix} \text{CAT} : v \\ \text{AGR} : \boxed{2} \end{bmatrix} \begin{bmatrix} \text{CAT} : np \\ \text{AGR} : \boxed{3} \end{bmatrix}$$

The unification in the context of the rule's head with the second element of σ succeeds, and identifies the values $\boxed{2}$ of (occurring in the head of the rule) and $\boxed{1}$ (occurring in the selected element of σ). The rule's body can then replace the selected element, resulting in a new sentential form:

$$\begin{bmatrix} \text{CAT} : np \\ \text{AGR} : \boxed{1} \end{bmatrix} \begin{bmatrix} \text{CAT} : v \\ \text{AGR} : \boxed{1} \end{bmatrix} \begin{bmatrix} \text{CAT} : np \\ \text{AGR} : \boxed{3} \end{bmatrix}$$

Similarly, the concept of derivation trees can be naturally extended to unification grammars. Example (13) depicts such a tree, where the scope of variable is extended to the entire tree.

(13) An example derivation tree:

To determine whether a sequence of words, $w = a_1 \cdots a_n$, is in the language of a grammar G, $L(G)$, consider a derivation in G whose first form consists of the start symbol (a feature structure, viewed as a form of length 1), and whose last form is σ'. Let σ be a form obtained by concatenating $A_1, \ldots, A_n$, where each A_i is a lexical entry of the word a_i. Of course, the length of σ is required to be exactly n (the length of w). Notice that, as words can be ambiguous, there can be more than one member in the lexical entry of a word; the definition only requires that one such AVM is selected for each word. $w \in L(G)$ if and only if σ' is a *multi-AVM* that is unifiable with σ: $\sigma \sqcup \sigma'$ does not

fail. The reason for taking σ' rather than σ in the definition has to do with the properties of unification. A derivation might end with an underspecified *multi-AVM*, where additional information has to be gathered from the lexicon; but the reentrancies in the final form of the derivation must be respected: arbitrary instantiations for the variables in this final form cannot be permitted. Rather, if a variable is instantiated to some value (by one lexical entry), all other occurrences of the same variable must be consistent with that value. The current definition takes care of this requirement.

The extension of CFGs by adding features to lexical items and grammar categories dates back to the 1970s (Kay, 1979) and was incorporated into various linguistic theories, starting with functional grammars, later called unification grammars and then functional-unification grammars (Kay, 1983) and lexical-functional grammars (LFG) (Kaplan and Bresnan, 1982; Dalrymple *et al.*, 1995). Later, it was the underlying formalism for Generalized Phrase-Structure Grammars (GPSG) (Gazdar *et al.*, 1985). The best introductory text with an informal, elementary discussion of feature structures is Shieber (1986). In addition to giving a rather informal characterization of feature structures, subsumption and unification, Shieber (1986) defines the simplest unification-based grammatical formalism, PATR (Shieber *et al.*, 1983), and demonstrates how it can be used to encode grammars in different linguistic theories. A linguistically motivated comparative survey of three theories, namely Government and Binding, GPSG, and LFG is given in Sells (1988). Nonrecursive feature structures were added to the tree-adjoining grammar (TAG) formalism (Joshi *et al.*, 1975) by Vijay-Shanker and Joshi (1991), and to some variants of categorial grammars by Uszkoreit (1986) and Zeevat *et al.* (1987). A clear introduction to contemporary phrase structure grammars, with an extensive description of both GPSG and HPSG, including their handling of various linguistic phenomena, is found in Borsley (1996). A more recent exposition of syntactic theory in terms of (typed) unification grammars is found in Sag and Wasow (1999).

Parsing with Unification Grammars

Unification grammars not only provide better linguistic generalizations than CFGs, they actually define a completely different class of languages. While CFGs are limited to defining context-free languages, unification grammars can generate the entire class of recursively enumerable languages, or in other words, can simulate the operation of a Turing machine. In this respect, unification grammars are very similar to programming languages.

The extended expressive power is a double-edged sword. It provides the grammar designer with extremely powerful means for expressing linguistic phenomena; but it is also equally easy to design grammars that never terminate: the computational process of *parsing*, whose aim is to produce all the grammatical structures that a grammar induces on a given sentence, is not guaranteed to terminate for all grammars.

Parsing with unification grammars was developed along with the increased popularity of these grammars at the beginning of the 1980s. A large variety of parsing algorithms have been adapted to unification grammars (Tomita, 1991; Bouma and van Noord, 1993; Sikkel, 1997). Pereira and Warren (1983) define parsing as a special case of logical deducation, and show how definite clause grammars in particular and other unification formalisms in general can be parsed using the Earley deduction proof procedure. The paradigm of parsing as deduction was later extended to many parsing strategies and a variety of grammar formalisms by Shieber *et al.* (1995).

However, it was immediately observed that general unification grammars are Turing-equivalent; this is first mentioned by Kaplan and Bresnan (1982) and is formally proven by Johnson (1988) and Shieber (1992). The main reason is that with unification grammars, ε-rules (rules whose body is empty) and unit-rules (whose body consists of a single element) cannot be removed from the grammar, as is the case with context-free grammars. This leads to derivations in which an unbounded amount of material is generated without expanding the frontier word. To rule out offensive grammars, Pereira and Warren (1983) define the concept of off-line parsability for definite clause grammars, having been introduced (unnamed) by Kaplan and Bresnan (1982) for LFG grammars. Several alternative definitions for this concept are available in the literature, each capturing slightly different properties of the constraint on grammars; a thorough survey is provided by Jaeger *et al.* (2005).

In spite of their inherent computational complexity, unification grammars have become widespread in computational linguistics due to their appealing expressivity and ability to provide detailed accounts of a wide variety of linguistic phenomena, from phonology and morphology to syntax and semantics. Several computational frameworks provide the grammar designer with environments for grammar development; among the most common are LKB (Copestake, 1999) and ALE (Carpenter and Penn, 1999). These systems have been successfully used for developing

large-scale, linguistically motivated grammars of a variety of natural languages.

United Arab Emirates: Language Situation

Editorial Team

© 2006 Elsevier Ltd. All rights reserved.

The United Arab Emirates (UAE) were formed by seven Persian Gulf states – Abu Dhabi, Dubai, Ajman, Fujairah, Ras al Khaimah, Sharjah, and Umm al Qaiwain – after independence from Britain in the early 1970s. The main source of income of the UAE is from oil production, and the economic success resulting from this, as well as a highly developed infrastructure and the comparatively liberal political climate, has attracted a large community of foreign nationals to the UAE, accounting for more than half of the population.

The official language of the UAE is Arabic. As in other parts of the Arabic-speaking world, the language situation in the UAE is characterized by diglossia: the non-native Modern Standard Arabic (Arabic, Standard) is used in writing and in speech for official, public, or formal situations, while colloquial Gulf Arabic (Arabic, Gulf Spoken) is the first language of (UAE nationals) native speakers of Arabic and is used in everyday speech. Arabic is used in all spheres of life, in government, business, the media, and education. Adult literacy in 2002 was 77.3%, and youth literacy (ages 15–24) was 91.4%. English is the main foreign language taught in public education and is used as language of instruction for teaching some subjects in tertiary education.

The population of the UAE is 2.9 million (2002 estimate), of which more than half are non-nationals. The largest group of foreign residents in the UAE are from South Asia, followed by migrants from Iran, other Arab countries, South East Asia, and Europe and East Asia. Languages spoken by more than 100 000 speakers (est.) in the UAE include Malayalam, Balochi (Balochi, Southern), Pashto (Pashto, Northern), Egyptian Arabic (Arabic, Egyptian Spoken), and Somali. Bengali, Telugu, Persian (Farsi, Western), Tagalog, and Omani Arabic (Arabic, Omani Spoken) are spoken by more than 50 000 speakers (est.) in the UAE (Grimes, 2004). No estimates are available for the number of speakers of Hindi, Urdu, Gujarati, or Panjabi. In addition, numerous smaller language communities, including speakers of Thai and Swahili, exist.

Language use of the media in the UAE reflect the multilingual situation; in addition to Arabic language print media and several TV and radio stations, a number of radio stations broadcast in English, Hindi, Urdu, and Malayalam.

United Kingdom: Language Situation

E K Brown, University of Cambridge, Cambridge, UK

© 2006 Elsevier Ltd. All rights reserved.

This article is concerned with the remarkably rich and complex linguistic situation in England, Northern Ireland, and Scotland. These three countries together with Wales comprise the United Kingdom of Great Britain and Northern Ireland. Separate articles deal with Wales (*see* **Wales: Language Situation**), the Channel Islands (*see* **Channel Islands: Language Situation**), and the Isle of Man (*see* **Isle of Man: Language Situation**).

The CIA World Factbook (2004) estimated that the population of the United Kingdom was 60 270 708 in 2004. English is the official language of the United Kingdom and the first language of the large majority of the population. There are no reliable data on the number of people whose first language is not English. According to the CIA Factbook (2004), the population comprises the following 'ethnic groups': English 81.5%, Scottish 9.6%, Irish 2.4%, Welsh 1.9%, Ulster 1.8%, and West Indian, Indian, Pakistani, and other 2.8%. In 2001, the Department for Education and Skills declared that at least 3 million people living in the United Kingdom were born in countries where English is not the national language.

There is great linguistic diversity in the United Kingdom (see Trudgill, 1984). The native languages are themselves varied – English and Scots are Germanic languages, and Welsh, Gaelic, Irish, and Cornish are Celtic languages – and the large number of other languages are the result of substantial immigration into the United Kingdom over many centuries from former European colonies, from Europe, and from much of the rest of the world. Some, like the Romani communities, are long established, but the majority have entered since the 1940s either as political refugees or as migrant labor (see Stubbs, 1985). Unfortunately, the national population census does not ask a question about language. The census team did, however, need to decide which languages the census forms and information leaflets needed to be translated into, and after consultation, the forms were translated into the following 24 languages (in alphabetical order): Albanian/Kosovan, Arabic, Bengali, Chinese (Cantonese), Croatian, Farsi, Persian, French, German, Greek, Gujerati (Gujarati), 'Hindi, Italian, Japanese, Polish, Portuguese, Punjabi (Panjabi), Russian, Serbian, Somali, Spanish, Swahili, Turkish, Urdu, and Vietnamese.

England

English is, by a very long way, the dominant language of the British Isles. Most of the population are native speakers, and almost all of those who are not have English as a second language. Other articles deal with the history of English, with English varieties and dialects, and with the dispersion of English through the world. This short section concentrates on the 'other' languages of England.

As noted above, there is no systematic enumeration of these other languages, but some idea of their diversity can be gained from Baker and Eversley (2000). They reported on a survey of the languages claimed to be spoken by London schoolchildren. They estimated that London schoolchildren speak over 300 different languages and that 30% of all London school children speak a language other than English at home. The 'top 40' languages are English, Bengali & Sylheti, Panjabi, Gujarati, Hindi/Urdu, Turkish, Arabic, English-based Creoles, Yoruba, Somali, Cantonese, Greek, Akan, Portuguese, French, Spanish, Tamil, Farsi, Italian, Vietnamese, Igbo, French-based Creoles, Tagalog, Kurdish, Polish, Swahili, Lingala, Albanian, Luganda (Ganda), Ga, Tigrinya (Tigrigna), German, Japanese, Serbian/Croatian, Russian, Hebrew, Korean, Pashto, Amharic, and Sinhala.

The linguistic diversity of London is probably replicated to a greater or lesser extent elsewhere in the United Kingdom, especially in urban areas, though with a different proportional distribution of languages reflecting different settlement patterns in different regions.

In Cornwall a small number of people speak, read, or understand Cornish, a Brythonic Celtic language (*see* **Cornish**). The United Kingdom has a long-established community of Romani speakers (*see* **Romani**). There are also speakers of Jewish English, Yinglish (*see* **Jewish Languages**).

The main languages taught in school are French, German, Spanish, and Italian. A dozen other languages, including some of the 'minority' languages listed above, are taught as part of the school curriculum in various parts of the country, reflecting local community demand. Many minority and community languages are also taught outside the school curriculum either by local authorities or by community groups. The language of the national media – visual, spoken, and written – is predominantly English, though there are numerous newspapers and other media in a wide range of other languages.

Northern Ireland

The population of Northern Ireland was estimated in 2002 at 1 696 641 (McKernan, 2004). English is the official language in public domains. The local dialects can be categorized as 'more English' or 'more Scots,' depending on the way in which English was imported into Ireland (see Harris, 1984). The more northerly dialects, spoken in parts of Antrim, Down, and Derry and sometimes referred to as 'Scotch-Irish,' reflect settlement from Scotland in the 17th century and are related to Lowland Scots. In 1999, Foras na Gaeilge and Tha Boord o Ulstèr-Scotch were created to promote the language. The dialects of Tyrone, Armagh, Down, and parts of Derry form 'Mid Ulster English' or 'Hiberno-English,' derive from settlement from England, and have more in common with English dialects. Hiberno-English is the dominant variety in Ulster and is spoken in Belfast. Native Irish died out around 1970; since the 1990s, there has been a growing Irish revival movement, and in the 2001 census, 10.35% of the population claimed to have some knowledge of Irish (i.e., could read, write, or speak Irish).

The European Charter for Regional or Minority Languages was signed in 2000 by the U.K. government with regard to Irish and Ulster Scots in Northern Ireland. It ratified the charter in the following year, acknowledging that provisions were in place to promote and develop Irish and Ulster Scots in Northern Ireland. Despite that ratification, Ulster Scots has been denied equal status with Irish. English is the dominant language of education, though in 1995–1996, 3% of primary school students were taught in the Irish medium. As in England, the main foreign languages taught in secondary schools are French, German, Spanish, and Italian. English is the dominant language of the media.

Scotland

The population of Scotland was recorded in the 2001 census as 5 062 011. English is the official language in public domains. In speech, a 'Scottish accent' of English is characterized most noticeably by rhoticity and by a loss of the vowel length distinctions found in most accents of southern England. There are also pervasive differences in vocabulary and idiom, as well as some small syntactic differences. 'Scottish English' exists in a continuum with the dialects known collectively as Scots: 'Lowland Scots' in the border regions and 'Doric' in the northeast. The most conservative dialects are to be found in the northeast and in the Northern Isles (see Aitken, 1984; Bergs, 2001). In the cities, notably in Glasgow, there is a lively working-class demotic form of speech (see Macafee, 1983). Many speakers switch among English, Scottish English, and Scots, depending on the situation. Scots is not officially recognized by the U.K. government, but the Scottish Executive's National Cultural Strategy contains a section promoting Scotland's languages, and there are vigorous and long-standing institutions that support and promote Scots. The General Register office (Scotland) has estimated that 30% of the population are Scots speakers. Scots is also vividly alive as a literary language supported by numerous independent publishing houses situated within the country (*see* **Scots**).

Gaelic, which suffered a catastrophic decline continuing into the early part of the last century, is being reinvigorated. The 2001 census recorded 1.9% of the population as speaking, reading, or understanding Gaelic; the language is particularly strong in the Western Isles where the census recorded that 71.6% of the population speak Gaelic. Gaelic is taught in universities, and a small but increasing number of primary schools offer Gaelic medium education. The BBC and independent TV stations offer Gaelic on TV and the radio. Gaelic is recognized as a minority language by the European Union (*see* **Scots Gaelic**).

The European Charter for Regional or Minority Languages was signed in 2000 by the U.K. government with regard to Gaelic and Scots in Scotland. As with Ulster Scots, the government ratified the charter, but Scots was denied equal status with Gaelic.

In Scotland, there are also several well-established immigrant communities, the largest from the Indian subcontinent and South Asia. There are also long-standing immigrant communities from Europe (e.g., Polish and Ukrainian).

Wales

The 2003 population estimate was that 2 938 000 people reside in Wales. Most of the south of the country is totally anglicized, but there are substantial Welsh-speaking areas in the north and west (*see* **Welsh**). The 2001 census recorded that 16% of the population claimed to understand, speak, read, and write Welsh – that is, have the full range of skills (but without any indication of the level of ability or usage) – whereas 20.5% claimed to speak at least some Welsh (up from 18.5% in 1991). Few people are monolingual in Welsh. The highest proportion of Welsh speakers is found in Gwynedd in the north of the country where Welsh is a first language for a segment of the population. The lowest proportion is in Monmouthshire in the south.

Support for the language grew during the second half of the 20th century, along with the rise of nationalist political organizations, such as the political party Plaid Cymru, Cymdeithas yr Iaith Gymraeg (the Welsh Language Society), and the establishment of the Welsh Assembly. The Welsh Language Act of 1993 established a Welsh Language Board charged with 'promoting and facilitating' the use of Welsh. The language has greatly increased in prominence since the creation of the television channel S4C in November 1982, which broadcasts exclusively in Welsh during peak viewing hours, as does the BBC. Local government uses Welsh as an official language, public bodies issue official literature and publicity in Welsh versions, and all road signs in Wales are in English and Welsh, including the Welsh versions of place names. It is the ambition of the Welsh Assembly 'to create a truly bilingual Wales.' The U.K. government has ratified the European Charter for Minority or Regional Languages with regard to Welsh. The percentage of primary schools where Welsh is the sole or main medium of instruction rose from 14% in 1990 to 18% in 2000. In the more Welsh areas (notably Gwynedd and Dyfed), secondary school education is bilingual, and, since 1999, all secondary schools in Wales are obliged to offer the teaching of Welsh as a second language to all students under 16. The increase in Welsh language provision in education has greatly affected the number of Welsh speakers in the younger age groups, and over the last decade, there has been a substantial effort to promote and sustain the language across the whole spectrum of Welsh life, including education, lifelong learning, community regeneration, the arts, health care, business and enterprise, tourism, housing, and social care.

United States of America: Language Situation

D Sharma, King's College London, London, UK

© 2006 Elsevier Ltd. All rights reserved.

The linguistic landscape of the United States, though dominated by English, encompasses an unusual diversity of indigenous and immigrant languages. No federal law currently grants English the status of official language, but it is used for virtually all official and institutional functions. Americans tend to be relatively monolingual in English (82% in 2000, **Figure 1**), and Spanish (11%, **Figure 1**) and other languages (7%, **Figure 2**) have a minority status in terms of size of speech community and institutional support (**Figure 2**).

American English

Regional and Social Varieties

English was first established in America by permanent settlers in Jamestown, Virginia, in 1607. By 1780, the number of people of European and African origin had increased to 2.8 million but more than 20% of European Americans were still from non-English-speaking communities, predominantly German, Dutch, Swedish, Irish, and French. This heterogeneity influenced the lexical stock of American English (e.g., *bayou, caribou, prairie* (French); *cookie, waffle* (Dutch); *noodle, snorkel* (German); *corral, ranch* (Spanish)) as well as its regional dialect features; Minnesota English, for instance, bears traces of

Support for the language grew during the second half of the 20th century, along with the rise of nationalist political organizations, such as the political party Plaid Cymru, Cymdeithas yr Iaith Gymraeg (the Welsh Language Society), and the establishment of the Welsh Assembly. By 1780, the number of people of European and African origin had increased to 2.8 million but more than 20% of European Americans were still from non-English-speaking communities, predominantly German, Dutch, Swedish, Irish, and French. This heterogeneity influenced the lexical stock of American English (e.g., *bayou, caribou, prairie* (French); *cookie, waffle* (Dutch); *noodle, snorkel* (German); *corral, ranch* (Spanish)) as well as its regional dialect features; Minnesota English, for instance, bears traces of

Swedish phonology and syntax. German (German, Standard) once had a substantial presence, but native use is now primarily limited to the dialect of German known as Pennsylvania Dutch.

Standard American English is distinctive in its phonology (rhoticity, except in parts of the South and the Northeast; greater use of /æ/, e.g., *fast, can't*; intervocalic flapping of /t/, e.g., *butter, writer*; widespread leveling of the vowel distinction in *caught* and *cot,* except in the Northeast), syntax (simple past in perfect contexts, e.g., *Did you see that film yet?;* use of *gotten*), lexicon (*sidewalk, carpark, elevator, schmuck*), and spelling (*center, neighbor, analyze;* Noah Webster's *American Dictionary of the English Language* [1828] introduced many revisions). Early linguistic atlases (Kurath, 1949) used isoglosses of lexical variants such as *pail/bucket* to identify three primary English dialect divisions in the United States – South, North and, to a lesser extent, Midland – within which further minor dialect divisions occur. More recent studies of contemporary dialectal phonological systems continue to reflect these divisions; new dialects are now also beginning to coalesce in more recently settled parts of the West.

Early English-speaking settlers arrived from distinct dialect regions of England and as the frontier later shifted westward, their distinct speech patterns spread along conduits of travel (see Figure 3). While certain features of American English have been argued to originate in the dialects of Early Modern English that first came to America (e.g., rhoticity; use of /æ/; *gotten*; *mad* 'angry'; *fall* 'autumn'), most dialect distinctions were rapidly leveled through early admixture in settlements. The distinctive features of present-day American English dialects therefore tend to derive more from ongoing language change than from early British English.

Pioneering work by William Labov and other sociolinguists, beginning in the 1960s, has demonstrated that social groupings are also a key factor in American dialects. For instance, the Northern Cities Vowel shift – a series of shifts in pronunciation in the area encompassing Detroit, Chicago, Buffalo, and Cleveland – results in certain linguistic features that function as social markers of class, ethnicity, age, and gender, and the associated prestige or stigma of such markers effects dialect change. This research has also indicated that despite the influence of media certain dialect boundaries, e.g., the North–South division, are strengthening in some respects.

African-American English

The variety spoken by many African Americans bears several defining linguistic features in its phonology (word-final consonant cluster simplification, e.g., *told, best;* use of /t, d, f, v/ for /θ, ð/, e.g., in *these,*

with, thumb, bath), syntax (invariant *be* for habitual meaning; nonstandard auxiliary use of *been* and *done*; null copula, e.g., *He workin'*; negative inversion and multiple negation, e.g., *Ain't nobody told me nothing.*), lexicon, and styles of discourse (e.g., toasting, signifying, playing the dozens). Research has shown these features to be systematic and rule-governed, as in all dialects. British English and Creoles have both been proposed as possible origins.

In 1996, the linguistic status of African-American English came under public scrutiny as the Oakland School Board in California passed a resolution declaring a social and educational need to recognize that what they termed Ebonics was the primary language of many students in the county. Although the Linguistic Society of America passed a resolution affirming the importance of recognizing African-American Vernacular English as a systematic dialect, the intensity of the public debate surrounding the school board's resolution led to its ultimate dissolution. The controversy unmasked deeply opposed popular views on the cultural status of vernacular dialects.

The Debate over Bilingualism

Early supporters of installing English as the official language of the United States included Benjamin Franklin and Noah Webster, and the English-Only movement continues this effort. As of 2004, 23 states have adopted Official English laws. However, many English-Only claims, e.g., immigrant resistance to learning English and detrimental effects of bilingualism, have been discredited: research finds consistently high rates of language shift to English among immigrants (see Figure 4), and the popular belief during the first half of the 20th century that bilingualism was detrimental to intellectual development has received no empirical support. In 1968, the Title VII Bilingual Education Act allocated federal funds to children with special linguistic needs. The Official English movement resists measures of this sort, while the English Plus movement, advocating a more bilingual model for the United States, supports them.

Spanish in the United States

The arrival of Spanish in the United States predates that of English, and its development in the Southwest and the Northeast has followed distinct historical and demographic patterns.

Spanish colonization began in Florida with Juan Ponce de Léon's visit in 1513, and spread soon after to Louisiana and the Southwest, where it was administered by the Spanish Viceroyalty, with colonial Spanish remaining the local prestige language for almost two centuries. After the Mexican-American war, almost half of Mexico was ceded to the United States in 1848, including all of present-day California,

Nevada, and Utah and parts of Texas, New Mexico, Colorado, Arizona, and Wyoming. Sustained Mexican migration has continually reinforced the Spanish-speaking population of many of these states. The Southwestern states are now home to just under half of the Spanish-speaking population in the United States. Sometimes termed Chicano Spanish, the Southwestern variety bears characteristics of Mexican Spanish and American English. English influence can be seen in lexical innovations (e.g., *libreria* (not *biblioteca*) 'library'; *parientes* (not *padres*) 'parents'; *puchar* 'to push'; *fensa* 'fence'; *cama king* 'king-size bed'); English-based phonology (e.g., *moven* for *mueven*, 'they move') and syntax (phrasal constructions in place of complex morphology) are also common.

Spanish in the Northeast primarily originates from Puerto Rico, the Dominican Republic, Cuba, and Colombia. In 1898, after the Spanish-American war, Puerto Rico became a territory of the United States and was the first major source of Spanish-speaking immigration to the East Coast. The majority of other immigrants arrived later; Cuban refugee migration, for instance, rose dramatically after the 1959 coup. While some phonological traits of these varieties are shared, such as deletion or aspiration of syllable-final /s/, other regional distinctions may persist: e.g., dropping of syllable-final /l/ and /r/ (Cuban) and raspy velar /r/ (Puerto Rican). As colonial Spanish developed first in the Caribbean, the Northeastern United States varieties have brought many Native American, African, and Creole loans into American English, e.g., *canoe* (Native American), *banana* (African), *bodega* (Caribbean Spanish).

Due to extensive language shift to English, a continuum of societal bilingualism has emerged in Hispanic communities, ranging from fluency in Spanish to symbolic use of Spanish by English-dominant bilinguals. Alongside the influence of English on Spanish structure, this bilingualism has given rise, particularly among English-dominant bilinguals in the younger generation, to 'Spanglish,' a hybrid style consisting of proficient and sustained code-switching between Spanish and English. Chicano English, by contrast, is a variety of English with Spanish influence.

Indigenous Languages

Native American Languages

The languages indigenous to America have undergone extensive decimation through contact with sociopolitically empowered colonial languages. Legislation punishing instruction or use of native languages and mandating English as the exclusive language of instruction was enforced in Indian reservations from the 19th century. Estimates place the number of native languages at the time of European contact at 300–600; the current figure stands at approximately 175, of which fewer than 20 are being acquired by children and are thus potentially sustainable. Over 70% of contemporary Native American languages face imminent extinction. A revitalization movement ultimately led to the Native American Languages Act of 1992, calling for federal policy to support the cultural vitality of Native American languages and authorizing funds for their maintenance.

American Creoles

New creole languages have developed indigenously in South Carolina, Hawaii, and Louisiana. In South Carolina, a creole called Gullah or Geechee (Sea Island Creole English) began to develop in 1715 when importation of African slaves, speaking different African languages natively, increased sharply in that area. Grammatical features of the variety include: pronouns such as *ee*, *um*, *shum*, *una*; *duh* or *does be* for habitual marking; *done* to mark completed actions; null copula, null possessive, and null simple past tense. Gullah has declined in recent decades, surviving in a few coastal enclaves. As it is relegated to the home, children may speak it natively but rapidly become bilingual.

Hawaiian Creole (Hawai'i Creole English), sometimes referred to as Pidgin, began to emerge between 1790 and 1820 through contact between native Hawaiians and Europeans; this development preceded a rise in Chinese, Portuguese, and Japanese arrivals between 1860–1900, followed by further influence from Filipino (Tagalog) and American English. These waves of contact resulted in a heterogeneous developmental process, particularly via informal and covert interaction among young speakers having English forcibly imposed on them in schools. Hawaiian Creole is characterized, among other things, by innovations in syntax (e.g., aspect marking: *stei* for progressive, *wen* for past) and in the lexicon, e.g., *pau* 'finished' (Hawaiian), *obake* 'ghost' (Japanese). Despite controversy over its societal and institutional role – only English and Hawaiian are official state languages – Hawaiian Creole is spoken and positively valued by a substantial community.

Louisiana Creole (Louisiana Creole French) is sometimes described as originally one of three French-based languages in Louisiana, alongside Cajun French (French, Cajun), brought by Acadians expelled from Nova Scotia in the 18th century, and Colonial French, an extinct variety once used by French colonizers. An alternative view treats the language situation as comprising a continuum ranging from more French to more

Creole usage. The Creole arose out of contact between African slaves and French colonizers during the period of 1699 and 1750; today, due to the greater social status of English and Standard French, all Louisiana Creole speakers speak another language outside their private domains.

American Sign Language

American Sign Language (ASL) is a natural, visual-spatial language not based on American English. In 1817, the first American school for the Deaf was established, and the resulting convergence of several varieties gave rise to an expanded contact variety. By the late 19th century, an oralist movement led to the banning of signing, a situation that persisted until the 1970s. ASL use nevertheless continued throughout, sometimes covertly, and ASL is now used by 0.5–2 million people, with considerable regional and social variation.

Minority Immigrant Languages

Commonly spoken immigrant languages in the United States other than English and Spanish are listed in Figure 2, which shows immigration-driven reversals in language use during the 1990s: a dramatic increase in the use of Russian (192%), Vietnamese (99%), Arabic (74%), Chinese (62%) and Spanish (57%) contrasts with the decline in the use of several European languages.

European languages have been replenished by immigration since the earliest arrivals in the 15th century. The first large-scale migration of unskilled Asian laborers occurred in the mid–19th century. Chinese, Japanese, and Korean enclaves formed, while South Asian and Filipino immigrants, fewer in number of largely male, did not form self-sufficient communities as early. The second wave of Asian immigration, when quotas were extended after 1965, included refugees from Cambodia, Vietnam, and Laos as well as descendants of earlier immigrants, often more educated and economically secure than their predecessors. The majority of early Arab American immigrants were Christian; subsequent to the 1950s, there has been a rise in Muslim Arab immigration, although this group remains a minority. The major varieties of Arabic represented are Lebanese and Syrian (Arabic, North Levantine Spoken), Palestinian (Arabic, South Levantine Spoken), Egyptian (Arabic, Egyptian Spoken), and Iraqi (Arabic, Mesopotamian Spoken).

Among speakers of minority immigrant languages, or 'heritage languages,' fluency declines sharply across generations, transitioning to monolingualism within two to three generations. In particular, attrition of fluency in selected registers, shift from balanced to asymmetrical bilingualism, and decline in biliteracy across generations is widespread, largely due to institutionalized monolingualism in schools. López's (1982) findings, shown in Figure 4, reflect a close correspondence between the nativeness of a generation in the United States and its tendency to be English-dominant. Nevertheless, language loyalty tends to be strong across generations; in particular, Figure 4 shows a lower rate of loss of Spanish among Mexican Americans as compared to some Asian languages. Language schools, ethnically-defined neighborhoods, and religious and cultural associations serve to maintain languages among first and second generation immigrants; third generation immigrants are generally English speakers but often show renewed, albeit often nonnative, interest in their heritage languages.

Universal Language Schemes in the 17th Century

D Cram, University of Oxford, Oxford, UK

In the mid-17th century there was widespread and intense interest in the prospect of creating a universal language based on strict philosophical principles. Such projects had a multiplicity of philosophical, theological, and pedagogical aims, ranging from the development of an instrument for establishing universal peace to the creation of a remedy for the 'curse of Babel' (i.e., the diversity of languages). Other more practical functions that such a language might serve included shorthand, cryptography, Bible translation, promotion of commerce, and improvement of education. The prospect of a universal language thus serves as a focal point for quite diverse linguistic concerns, and indeed there are few contemporary preoccupations concerning the unity and diversity of languages that are not directly or indirectly linked to it. This makes the schemes themselves of central importance to the historian of ideas as a unique window into to the 17th-century intellectual landscape. But the very diversity of the preoccupations that are thus brought together means that there is always a danger for the modern reader of oversimplifying the multidimensional historical background.

How the Schemes Worked

It was in England that the theoretical possibility of a universal language was pursued most as a practical challenge, and this makes a survey of the various English entrepreneurs a convenient introduction to how such schemes worked. In fact, the schemes ranged from the quite simple to the very elaborate, and it is useful to follow through a logical progression, using contemporary terminology: from a 'shorthand,' to a 'universal character,' to a 'real character,' to a 'philosophical language.' (Note that the 17th-century term 'character' here means a system of notation, or a writing system.)

Visitors to England in the 17th century were struck by the widespread use of shorthand, known at the time as 'brachygraphy' (i.e., 'short writing'). There were many systems of shorthand available, and they were used for purposes ranging from the transcription of sermons by the congregation to the writing of diaries. Private shorthand systems could also be used as secret codes, and their use for cryptographical purposes was given an extra boost by the turmoil of the civil war in the 1640s. With regard to their structural properties, most shorthand systems used a combination of alphabetic and logographic principles, where an alphabetical sign represented some phonetic element of a word, whereas a logograph represented the meaning of a word by means of a single nonphonetic sign: thus the three letters *s, i,* and *x* gave an alphabetical representation of the component sounds of the

Universal Language Schemes in the 17th Century

In the mid-17th century there was widespread and intense interest in the prospect of creating a universal language based on strict philosophical principles. Such projects had a multiplicity of philosophical, theological, and pedagogical aims, ranging from the development of an instrument for establishing universal peace to the creation of a remedy for the 'curse of Babel' (i.e., the diversity of languages). Other more practical functions that such a language might serve included shorthand, cryptography, Bible translation, promotion of commerce, and improvement of education. The prospect of a universal language thus serves as a focal point for quite diverse linguistic concerns, and indeed there are few contemporary preoccupations concerning the unity and diversity of languages that are not directly or indirectly linked to it. This makes the schemes themselves of central importance to the historian of ideas as a unique window into to the 17th-century intellectual landscape. But the very diversity of the preoccupations that are thus brought together means that there is always a danger for the modern reader of oversimplifying the multidimensional historical background.

How the Schemes Worked

It was in England that the theoretical possibility of a universal language was pursued most as a practical challenge, and this makes a survey of the various English entrepreneurs a convenient introduction to how such schemes worked. In fact, the schemes ranged from the quite simple to the very elaborate, and it is useful to follow through a logical progression, using contemporary terminology: from a 'shorthand,' to a 'universal character,' to a 'real character,' to a 'philosophical language.' (Note that the 17th-century term 'character' here means a system of notation, or a writing system.)

Visitors to England in the 17th century were struck by the widespread use of shorthand, known at the time as 'brachygraphy' (i.e., 'short writing'). There were many systems of shorthand available, and they were used for purposes ranging from the transcription of sermons by the congregation to the writing of diaries. Private shorthand systems could also be used as secret codes, and their use for cryptographical purposes was given an extra boost by the turmoil of the civil war in the 1640s. With regard to their structural properties, most shorthand systems used a combination of alphabetic and logographic principles, where an alphabetical sign represented some phonetic element of a word, whereas a logograph represented the meaning of a word by means of a single nonphonetic sign: thus the three letters *s, i,* and *x* gave an alphabetical representation of the component sounds of the

English word *six,* while the single logograph *6* represented the meaning of this word as a whole. In functional terms, this had the crucial consequence that while alphabetic systems were intrinsically language specific, a purely logographic script would also function as a universal character: a text in English that was transcribed using a logographic universal character could be back-translated not just into English but into French or any other arbitrary language (e.g., *6* translates as Welsh *chwech* as well as English *six*).

The first publications to present themselves as a 'universal character' were simple in the extreme. Cave Beck's scheme was little more than an English word list with a number assigned to each entry (plus a small number of grammatical particles); a parallel French word list had corresponding numbers to link translation equivalents (Beck, 1657). But contemporaries were quick to see the potential applications of such universal scripts in the context of scientific, diplomatic, and missionary activities. Texts, biblical or other, would not need to be translated multiple times; all that needed to be supplied was single translations into the universal character, along with a set of language-specific manuals by which they could be back-translated. Furthermore, a universal character that was **also** a shorthand would, of course, be doubly efficient.

The next stage was to transform the universal character into a 'real character' by constructing logographs not on a purely arbitrary basis (as with Beck). It was recognized that there were already scientific contexts where the limited use of such signs was internationally established: for example, the use of icons to represent the planets in astronomy and the various chemical elements in alchemy and medicine. All that was needed, in principle, was to extend such sorts of usage to the language as a whole. The development of these schemes is extremely interesting from a linguistic point of view, since their architectural principles are in effect hypotheses about the semantic structure of grammar and lexicon. Thus, in a pilot scheme devised by Francis Lodwyck, a radical symbol was assigned to the general concept *drink*, with modifying diacritics to distinguish the cluster of related items such as *drinker* AGENT, *drink* OBJECT, *drinking place* LOCATION, and so on (Lodwyck, 1652; ed. Salmon, 1972). Since the diacritics themselves recur with other radicals (for example, with *write* to yield the set *writer, thing written, writing place,* etc.). The principal idea was that in such a scheme the signs would not stand for words (in a language-specific sense) but would stand directly for things – hence the term 'real character' (cf. Latin *res* 'thing'). Furthermore, if properly constructed, the semantic makeup of such a sign would be transparent: in general, a simple notion would always be represented by a simple sign and a complex notion by a complex sign; and more particularly, a sign representing an agent would always contain the diacritic meaning *agent*, and vice versa.

A real character is by definition a system of writing. It could be turned into a full 'philosophical language' by assigning regular phonetic values to the rationally constructed signs. (Note that in 17th-century usage, the term 'philosophical' covered much that today would be called 'scientific.') A language developed along these lines would be fully adapted for scientific uses and, in a Judeo-Christian context, would amount to a reconstruction of the original language of Adam (with which it would be fully isomorphic, if it could not be identical). In short, it would be a 'perfect' language in the long-standing utopian sense (cf. Eco, 1995); and indeed, there seemed to be no reason in principle why it should not continue to function as a shorthand system, along with all its other advantages. However, the two authors who published a fully worked-out scheme, which they presented as a philosophical language (Dalgarno and Wilkins), took great pains to emphasize that their inventions were not specimens of perfect languages, and Dalgarno even explained at length why a language could not possibly be perfect in all respects.

Problems of Implementation

In a 17th-century English context, the purely philosophical appeal of a utopian language was amplified by larger sociopolitical resonances. It was intimately associated with missionary and imperialistic objectives; it was prominent in debates about the development of algebraic and taxonomic notations requisite in science and technology; and it carried strong millennial overtones that were themselves linked to the political upheavals of the civil war. However, while from a distance all these strands seem to run in the same direction toward a single linguistic objective, what in fact happened was that the technical problems that arose in the practical implementation of a philosophical language caused the skein to unravel. It turned out that not all the objectives were mutually compatible.

George Dalgarno (c. 1616–1687) seems to have been the first to spot that the objectives of a real character were not just incompatible with those of a shorthand system but were diametrically opposed to them. While the purpose of the latter was to abbreviate complex signs into simpler compendia, the aim of the former was precisely to ensure that signs that were semantically complex were transparently expanded to their fullest extent. One system of transcription cannot serve both

purposes. Furthermore, Dalgarno perceived that the results of logical analysis, which strictly speaking should be the foundation of what he considered a truly philosophical language, were in practice not usable as such. For supposing that concepts could be completely broken down into their basic constituents, and that expressions could be formed reflecting this analysis, the result would clash both with the cognitive habits and capacities of language users and with efficiency constraints on the length of expressions. In other words, a sign that properly and completely represented the complex concept it designated would often – far from being transparent – be both incomprehensible and unworkably long.

Other difficulties were to arise when it came to arriving at a consensus as regarded the philosophical principles on which the language was to be based. It had been conceived by many of those involved that the universal language scheme would perforce need to be a collective enterprise. George Dalgarno had at first worked together with Seth Ward and John Wallis on this basis, and he later collaborated closely with John Wilkins (1614–1672). But opinions on the method for constructing the lexicon of the philosophical language widened into a fundamental "breach of judgment," and not one but two schemes were to appear in print. In Wilkins's opinion, the number of radical words, on which modifiers such as those indicating AGENT were to be applied, should be several thousands. In addition, each of these radical words should be connected with a definite place in a comprehensive classification, so that the form of each word would indicate what sort of thing it referred to. In Dalgarno's opinion, Wilkins's method suffered from the attempt to force two incompatible goals – scientific classification and the creation of a practicable language – into a single design. Dalgarno insisted that the number of radical words should be much smaller, so that the language would be more flexible in enabling its users to form complex signs for logically complex things, for this flexibility remained his guiding principle in spite of his belief that it could not be completely carried through. Wilkins, in the preface to his *Essay towards a real character and a philosophical language* (1668; **Figure 1**), made only a passing and anonymous reference to his initial work with Dalgarno, whose *Ars Signorum* had appeared in 1661 (**Figure 2**).

Wilkins' *Essay* was published with the imprimatur of the recently founded Royal Society and was itself a collaborative work, having received input for the elaborate classification schemes it contained from various quarters, notably from John Ray and Francis Willoughby on natural history. After Wilkins' death in 1672, a committee of the Society was set up to look into ways in which the scheme might be improved and put into practice, and there was extensive correspondence within a circle that included Andrew Paschall, John Aubrey, Francis Lodwyck, Robert Hooke, and others. But the discussions were inconclusive, and by the 1680s it was apparent that the whole enterprise had run out of steam.

Questions of Motivation and Objective

Although the heyday of the 17th-century search for a universal language was thus comparatively short-lived, it was a pan-European rather than a narrowly British phenomenon. What emerges from a consideration of the larger context is the variety of the motivations that were involved. Thus, for example, the schemes that were developed in England appear to be by and large intrinsically linked with Protestant missionary objectives; it is emblematic that the frontispiece to Beck's real character should depict figures representing Asia, Africa, and America seated at a table and hearkening (as one might expect in such a context) to the words of a European. But not all those involved in Protestant Bible translation were persuaded of the viability of a universal language for these purposes; Robert Boyle, a leading promoter of missionary activities, was keen to inform himself of their progress, but remained profoundly skeptical. Neither, on the other hand, were universal language schemes a uniquely Protestant preoccupation, since similar schemes were developed and promoted by Jesuit scholars such as Athanasius Kircher and others.

Several of the major intellectual figures of the 17th century whose names are associated with universal language did not themselves produce practical schemes but issued programmatic calls that were taken up and elaborated by others. But although it is tempting to group these calls together as representing variants of a single agenda, they each need to be assessed carefully in the context of the larger philosophical program, and it often emerges that what was intended by a 'philosophical language' for one thinker was quite different from, and sometimes incompatible with, that of the next. Thus, the objectives outlined by Francis Bacon were couched in a scientific framework, which was radically different from that of the religious and pansophic reformer Jan Amos Comenius (Komensky), although Dalgarno linked the two names as mentors in the advertisements for his scheme (Dalgarno, 1657). And what Comenius understood by 'universal harmony,' which a universal language should promote, was fundamentally different from the meaning of the rubric of 'harmonie universelle' in the context of which Marin Mersenne made his own call for a

CHAP. II.

Instances of this Real Character in the Lords Prayer and the Creed.

FOr the better explaining of what hath been before delivered concerning a Real Character, it will be neceſſary to give ſome Example and Inſtance of it, which I ſhall do in the *Lords Prayer* and the *Creed*: Firſt ſetting each of them down after ſuch a manner as they are ordinarily to be written. Then the Characters at a greater diſtance from one another, for the more convenient figuring and inter lining of them. And laſtly, a Particular Explication of each Character out of the Philoſphical Tables, with a Verbal Interpretation of them in the Margin.

The Lords Prayer.

philosophical language. A more skeptical position on the possibility of a philosophical language was taken by René Descartes. Toward the end of the century, a number of the ideas that were in circulation were picked up and redeployed by Gottfried Wilhelm Leibniz.

Ars Signorum,

VULGO

CHARACTER UNIVERSALIS

ET

LINGUA PHILOSOPHICA.

Qa poterunt, homines diverſiſſimorum Idiomatum, ſpatio duarum ſeptimanarum, omnia Animi ſua ſenſa (in Rebus Familiaribus) non minus intelligibiliter, ſive ſcribendo, ſive loquendo, mutuo communicare, qam Linguis proprius Vernaculis. Excudebat *J. Hayes*, Sumptibus Authoris,
Anno reparatæ ſalutis, 1661.

Figure 2 George Dalgarno's universal language scheme of 1661.

Universal Language and Language Diversity

The above considerations show that discussions of a universal language in the 17th century were central to speculation about language of all sorts, not just about mathematical and logical notation for restricted scientific purposes, nor about simple equivalents to Esperanto. It is thus in the context of universal language schemes that one can find informed and perceptive contemporary discussion of language diversity and language change (for example, in the prefatory matter to Wilkins' *Essay*), and some interesting precursors of language typology in the modern sense.

A final note may serve to highlight both the difficulties and the interest of 17th-century universal

language schemes for the modern reader. In a modern context, the term 'natural language' contrasts with 'artificial language.' In a 17th-century context, a 'natural' language was one that was in conformity with nature, as was the (supposed) original Adamic language. A constructed philosophical language would thus be both artificial and also 'natural' in this sense. What corresponds to the modern concept of 'natural language' would, in a 17th-century context, be an 'instituted language' (i.e., a conventional one). It is of interest that the outcome of the exploration of universal language schemes was often a better understanding of 'instituted languages.' Thus, for example, Dalgarno's recognition that a 'universal character' cannot at the same time be both a shorthand system and a real character led him to the perceptive conclusion that instituted languages, such as English and French, are in effect shorthand systems, i.e., that their simplex words may express ideas that are semantically complex.

A broad history of the quest for a perfect language can be found in Eco (1995; but see the cautionary review by Cram and Maat, 2002). There is a rich bibliography of works available for the reader who is interested in the structural details of individuals schemes, ranging from the early study by Couturat and Leau (1903) to recent works that give access to the primary texts (e.g., Cram and Maat, 2001; Maat, 2004). For studies of the intellectual context of the English schemes, see Salmon (1972), Knowlson (1975), Slaughter (1982), and Lewis (2003). On the lexicological aspects of Wilkins' scheme, see Dolezal (1985), and see Subbiondo (1992) for a collection of studies of Wilkins' *Essay*.

Uralic Languages

A Marcantonio, University of Rome 'La Sapienza,' Rome, Italy

© 2006 Elsevier Ltd. All rights reserved.

The 'Uralic' languages derive their name from the Ural Mountains, the assumed homeland of the hypothetical proto-Uralic population that, according to the conventional theory, spanned out into Hungary and across a wide portion of the northern Eurasiatic area, from Norway to Western Siberia (see Figure 1).

Distribution

Of the 22 million speakers of Uralic languages, about 2 million are minority speakers in Russia. The total number of speakers is decreasing; some languages are endangered and others are now extinct. The Uralic language family can be divided into eight language subgroups:

1. Saami (formerly Lapp; 34 000 speakers); about 10 dialectal varieties are spoken in the region between Sweden and the Kola Peninsula in Russia.
2. Finnic (formerly Balto-Finnic), comprising Votic (about 50 speakers, Russia), Ingrian (400 speakers, Russia), Karelian (40 000 speakers, Finland and Russia), Lude (5000 speakers, Russia), Olonetsian (30 000 speakers, Finland and Russia), Veps (6000 speakers, Russia), Livonian (about 10 speakers, Latvia), Finnish (also called Suomi; about 5 500 000 speakers), and Estonian (about 1 000 000 speakers), including the Estonian ethnic/dialectal variety Vôru-Seto (50 000 speakers) in Estonia and Russia.
3. Mordvin (Mordva; 615 000 speakers, Russia), comprising two ethnic/dialectal varieties, Erzya (about 67%) and Moksha (about 33%).
4. Mari (formerly Cheremis; 488 000 speakers, Russia), comprising two dialectal varieties, Hill (Western) Mari (about 10%) and Meadow (Eastern) Mari (about 90%).
5. Permic, or Permian (Russia), comprising Udmurt (formerly Votyak; 464 000 speakers) and Komi, consisting of three ethnic/dialectal varieties, Komi-Zyrian (217 000 speakers), Komi-Permyak

Figure 1 The Uralic languages are spoken by 22 million people. The majority consist of the Finns, Hungarians, and Estonians, living in their nation-states; some 2 million speakers are among the ethnic minorites of Russia. Reproduced with permission from Suihkonen P (2000), *Ugriculture 2000: contemporary art of the Fenno-Ugrian peoples.* Helsinki: Gallen-Kellela Museum.

(94 000 speakers), and Yaz'va-Komi (about 200 speakers).
6. Ob-Ugric (Ob-Ugrian), comprising Mansi (formerly Vogul; 3000 speakers) and Khanty (formerly Ostyak; 14 000 speakers), scattered along the Ob' and lower-Irtysh rivers and tributaries.
7. Hungarian (Magyar; 14 million speakers), including the ethnic/dialectal variety Csángó (100 000 speakers, Romania).
8. Samoyed (Samoyedic), comprising seven closely related languages spoken in West Siberia, i.e., Nenets (formerly Yurak; 32 000 speakers), Enets (formerly Yenisey-Samoyed; about 200 speakers), Nganasan (formerly Tavgy; 1000 speakers), Selkup (formerly Ostyak-Samoyed; 2000 speakers), and three extinct languages, Yurats, Kamas (Kamassian), and Mator (Motor).

Hungarian and Ob-Ugric are conventionally grouped together to form the 'Ugric' subgroup, but the languages are acknowledged to be radically different in phonology, syntax, and vocabulary, and accordingly this group has not been reconstructed from the primary evidence. Several minority languages, including Veps, Mordvin, Mari, Udmurt, Komi, and Ob-Ugric, enjoy official status in their national administrative regions. Despite attempts to revitalize some endangered languages through cultural/educational/political activities and associations (e.g., 'Saami Language Nests' and 'To Save Yugra'), there remains strong pressure to assimilate into the majority languages (Suihkonen, 2002).

Phonology

Most Uralic languages display vowel harmony and consonant gradation, although there are substantial differences in implementation. These features are shared by nearby language groups, including Altaic and Yukaghir. Several Uralic languages also display quantitative vowel and consonant opposition.

Vowel Harmony

Palatovelar vowel harmony, in which the vowels of a word unit, including suffixes, enclitics, etc., are either all back or all front, is found in Finnic (not Estonian and Livonian), Mordvin, Western Mari, some Khanty and Mansi dialects, Hungarian, and Nganasan. Compare Hungarian *kert-be* 'garden-into', *kert-em-be* 'garden-my-into' and *konyhá-ba* 'kitchen-into', *konyhá-m-ba* 'kitchen-my-into'. Labial harmony occurs in Hungarian and Eastern Mari.

Consonant Gradation

Abondolo (1994: 4855) found that most Finnic and Saami languages/dialects display "alternation of strong vs. weak consonant(ism) word-medially in open vs. closed syllables." For example, in comparing Finnish *kirkko* 'church' vs. *kirko-ssa* 'church-INESS' (INESS = inessive) and *papu* 'bean' vs. *pavu-t* 'bean-PL', the first sound of each pair, the strong grade, appears word medially in an open syllable, whereas the second sound, the weak grade, appears word medially in a syllable closed by a suffix. The Samoyed languages display a different, less homogeneous type of gradation. For example, Nganasan presents a complex co-occurrence of various mechanisms, including glottal stop alternation, truncation, syllabic and rhythmic gradation, vowel harmony, and accommodation. In some languages, within specific contexts and/or stems, the original phonetic conditioning factor for gradation has been eroded by subsequent changes; therefore, several inflectional forms can now be distinguished through grade alternation only ('fusion'). Compare the nominative (NOM), genitive (GEN), and partitive (PARTIT) in Finnish *jalka-Ø* 'foot-NOM', *jala-n* 'foot-GEN', and *jalka-a* 'foot-PARTIT' with correspondent Estonian *jala-Ø* (genitive, weak grade) and *jalga-Ø* (partitive, strong grade), in which the alternation is no longer productive.

Vocalism

The smallest vowel inventory (five vowels) is found in Erzya Mordvin; the richest inventory is found in Vakh Khanty, which has 11 full and 2 reduced, front and back (round and unround) vowels. There are diphthongs in Finnic, Saami, some dialects of Mansi, and Nganasan. In several languages, some vowels occur less frequently when not in the first syllable. Most languages (not Erzya Mordvin and most of Permian) present (some sort of) quantitative vowel opposition between two (e.g., Finnish) or three (e.g., Estonian) vowel lengths, to denote different meanings.

Consonantism

Consonantism varies considerably. Finnish has one of the smallest inventories, with 11 consonants, the obstruents being limited to the unvoiced *p, t, k*. Eastern Enontekiö (North Saami dialect) has 31 consonants; the total inventory includes voiced stops, unvoiced nasals, fricatives, affricates, palatal (or palatalized alveolar/dental) series, glides, and laryngeal and glottal stops. Several languages present quantitative consonant opposition between two-way (e.g., Finnish) or three-way (e.g., Estonian and partly Saami) opposition, to denote different meanings. Unlike the other Uralic languages, Hungarian, Permic, and (to a lesser extent) Saami display opposition of voice – for example, voiced *b* and unvoiced *p* denote different meanings.

Word Stress

The stress position varies from language to language, the governing rules often being complex or conditioned by morphophonology or phonotactics. For example, stress is fixed on the first syllable in Finnish, Hungarian, and some Khanty dialects; it is free in Erzya Mordvin, and it falls generally on the last syllable in Udmurt and on the penultimate vowel/vowel sequence in Nganasan. In Nenets, stress position varies depending on morphophonological/syllabic structure. Stress is nondistinctive, except in Udmurt in certain forms.

Morphology

The Uralic languages share -Ø subject marking and a tendency for agglutination, suffixation, absence of copula, and richness of derivational morphology (Abondolo, 1998). These properties are also shared with Altaic. Grammatical, functional, and temporal/aspectual categories are generally language specific, with evidence from historical documents and language examination indicating relatively recent formation. Fusion (see the preceding discussion of consonant gradation) also occurs in varying degrees in several languages, including Estonian, Saami, and Hungarian.

Case Suffixes

The number of case suffixes varies from two (lative and locative) in Northern Khanty to 24 in Komi-Zyrian. In languages with rich suffixation, the majority of suffixes are local suffixes expressing three-way spatial opposition, as in stasis vs. movement ('to' and 'from'). This may be enriched by other suffixes indicating internal vs. external notions in Finnic and Permic. In Hungarian, the additional notion of vicinity is also encoded, as in *ház-ban* 'house-in (side)', *ház-ba* 'house(inside)-into', and *ház-ból* 'house(inside)-from'; *asztal-on* 'table-on', *asztal-ra* 'table(surface-of)-onto', and *asztal-ról* 'table(surface-of)-from'; and *szobor-nál* 'statue-in(the vicinity of)', *szobor-hoz* 'statue(the-vicinity-of)-toward', and *szobor-tól* 'statue(the-vicinity-of)-from'. In Komi-Zyrian and Selkup, the case suffixes also encode animacy.

Plural Markers

Plural markers also vary across the languages, some having a different marker for oblique and/or possessive forms. In Finnish, compare *talo-t* 'house-PL' and *talo-i-ssa* 'house-PL-INESS, in (the) houses'; in Hungarian, compare *birká-k* 'sheep-PL' and *birká-i-m* 'sheep-PL-POSS, my sheep'. The most common plural suffixes are *-t*, *-n*, and *-l*. Saami, Ob-Ugric, and Samoyed have dual suffixes.

Gender and Definiteness

As in Altaic languages, Uralic languages make no gender distinction (except in some nominal derivations), and there are no articles (except in Modern Hungarian); pragmatic and referential notions are typically expressed through the morphological and morphosyntactic apparatus. Mordvin distinguishes indefinite and definite forms of the noun.

Verbs

Verbs are inflected for person, number, tense/aspect, and mood. Typically, there is at least a distinction between present (unmarked) and past tense (marked) and between indicative, imperative, and conditional (except in Mansi). Some languages (e.g., Estonian, Udmurt, and Selkup) also encode the category of evidentiality as mood and/or tense. Reflexivity and causativity are mostly expressed through verbal derivation.

Negation is mostly (although not in Estonian, Hungarian, Ob-Ugric, and Selkup) expressed by an auxiliary (AUX) negation verb, regularly inflected, followed by the main verb, as in the following examples in Finnish:

(1) e-**n** mene
AUX–1SING.PRES go
'I do not go'.

(2) e-**t** mene
AUX–2SING.PRES go
'You do not go'.

Aspect is expressed by various means, including coverbal adverbs, auxiliary verbs, or appropriate marking for the direct object. Compare the different object marking in Finnish:

(3) lue-n artikkeli-**a**
read-I article-PARTIT
'I am reading a/the article'.

(4) lue-n artikkeli-**n**
read-I article-ACC
'I will read the article (completely)'.

Syntax

In the Uralic languages, word order, diathesis, number agreement in noun phrases, and subordinate sentence implementations are generally language specific. In common with Altaic languages, Uralic languages share the following tendencies: postpositions, modifier(s) preceding the modified element within noun phrases, marking as singular all nouns preceded

by any numeral, and expression of subordination through nominalized/nonfinite verbal phrases (Finnish and Hungarian have recently developed subordination through conjunctions).

Basic Word Order

Saami, Finnish, Estonian, Komi, and Hungarian present as subject-verb-object (SVO); Udmurt, Ob-Ugric, and Samoyed present as subject-object-verb (SOV); Mari has a flexible order. Pragmatic/logic/stylistic functions usually play a role in determining word order.

Main Verb Phrases

Verbal phrases may be elaborated in various ways. Ob-Ugric has a passive (personal) voice – e.g., the agent is marked in Khanty by locative. Finnish uses an impersonal passive, and the agent is unspecified. In some languages, extra conjugations encode information about the object, such as number, definiteness, topicality, and referentiality. Hungarian adds one objective/definite (DEF) conjugation to the normal subjective/indefinite (INDEF) conjugation (ACC, accusative):

(5) olvaso-**k**
read–1SING.INDEF
'I read (something)'.

(6) olvaso-**m**
read–1SING.DEF
'I read it'.

(7) olvaso-m a könyv-et
read–1SING.DEF the book-ACC
'I read the book'.

Ob-Ugric adds three objective conjugations, for singular, dual, and plural objects. Nenets, Enets, and Nganasan have five conjugations: one subjective, three objective (as Ob-Ugric), and one objectless/reflexive. The markers differ.

Subordinate Sentences

There are several types of nonfinite (participial, infinitival, and gerundive) verbal phrases. Typically, the verb takes the relevant nonfinite morpheme, and then may be inflected with enclitics, and case, number, possessive, and passive suffixes. Compare Finnish, in which *-ä* (∼ *-a*) and *-ma* (∼ *-mä*) are infinitive morphemes (TRANSLV, translative; EL, elative):

(8) syö-mme elä-ä-kse-mme
eat–1PL live-INF-TRANSLV–1PL
'We eat to live'.

(9) Pekka on koto-na leikki-mä-ssä
Pekka is home-at play-INF-INESS
'Pekka is at home playing'.

(10) Pekka tuli puutarha-sta ä-stä
Pekka came garden-from play-INF-EL
'Pekka came from the garden from playing/ where he was playing'.

Objects

Marking of the direct object is varied and complex, often depending on pragmatic/aspectual factors (as in Examples (3) and (4)), or on the type of sentence the object is in – for example, Hungarian has *-t*, Khanty and Sosva Mansi have -Ø, Eastern Mari and some Samoyed languages have *-m*, Finnish has *-n* or partitive for singular and -Ø or partitive for plural objects, and Udmurt has -Ø for indefinite and accusative for definite objects. Number agreement occurs between subject and predicate. Within the noun phrase, agreement in number and case suffixes occurs in some languages and to various degrees of completeness, being fully developed in Finnish.

Uralic Languages as a Family

The results of recent archaeological, genetic, and anthropological research are inconsistent with the predictions of the Uralic theory, and the significance of the linguistic evidence on which the conventional theory is based has been called into question: for example, there is no reconstruction of the key Ugric node based on the primary evidence, and the common linguistic tendencies appear to be shared with other language groups, such as Altaic. Alternative models have been proposed (see Künnap, 2000; Marácz, 2004; Marcantonio, 2002; Wiik, 2002).

Urdu is the literary, cultural, and religious language of Muslims in India, Pakistan, Bangladesh, and other parts of the world including the United States, the United Kingdom, Germany, and Sweden. The number of Urdu speakers in census data may be under- or overestimated for social and political reasons. However, it is estimated that Urdu is spoken by 54 million worldwide, out of which 43 million speakers are found in India. In addition to being the national language of Pakistan, Urdu is one of the Schedule VIII languages of the Indian democracy, the state official language of Jammu and Kashmir, and the second official language of UP, Bihar, and Andhra Pradesh in India. It is recognized that Urdu, Hindi, and Hindustani share a common grammatical system. Urdu in its colloquial form may therefore be considered the lingua franca of one of the largest speech communities in the world. Urdu is regarded as a pluricentric language that shows different linguistic features.

Origin and Development

Historically, Urdu has developed in a language contact situation over a long period from 1100 A.D. or earlier. After the Muslim invasion of India, it emerged as a speech variety in communication among Muslim rulers, traders, mystics, and the local population. The early form of Urdu developed out of the literary language Sauraseni Apabraṃsa, which was in a state of transition and developing as a New Indo-Aryan language. It had a wide dialect base that included Braj Bhasha, Haryanvi or Bangaru, eastern Panjabi, and other dialects spoken in the region surrounding Delhi. Khaṛi Boli was present as one of the elements in the formative period of Urdu and it gradually became stronger with its development. By 1800, Khaṛi Boli could be considered as the basic source of Urdu. During the period of development, from 1100 to 1800 A.D., Urdu was known by several different names, including Hindwi, Dehalvi, Hindustani, Zaban-e-Urdu, Dakhini or Old Urdu, and Rekhta. The first use of the language name Urdu was made in a couplet in 1776 by the poet Mashafi (1750–1824). However, the use of Urdu, referring to camp, court, or city (Zaban-e-Urdu or Zaban-e-Urdu-e-Shahi or Zaban-e-Urdu-e-Mualla), had been in use from 1560.

Specimens of Hindwi in the early formative period are found scattered in the Nath Panthi literature, early Sufis of North India, Amir Khusro, Nanak, Kabir, Baba Farid, and other poets. Amir Khusro (1236–1324) shows a distinct earlier form of Urdu, or Hindwi as he calls it. However, there is no evidence that the language was in continuous use from 1200 to 1650 except *Bikat Kahani* by Afzal, which appeared 300 years after Amir Khusro's writings. It is therefore not possible to reconstruct a continuous history of the development of Urdu (Chatterji, 1960; Khan, 1958). Insha Allah Khan Insha's *Darya-e-Latafat* ('The river of elegance,' 1807) presents an early linguistic study of the dialects of Delhi and Lucknow.

The emergent variety Hindwi traveled in the south with the Muslim rulers of the Delhi Sultanate (1211–1504) along with the Muslim armies, traders, Sufis, preachers, and other people. It flourished as a literary language in the Decean kingdoms of Golkunda and Bijapur. It was popularly known as Dakhini or Hindwi or Dehalvi. Dakhini has been claimed as

Urdu is the literary, cultural, and religious language of Muslims in India, Pakistan, Bangladesh, and other parts of the world including the United States, the United Kingdom, Germany, and Sweden. The number of Urdu speakers in census data may be under- or overestimated for social and political reasons. However, it is estimated that Urdu is spoken by 54 million worldwide, out of which 43 million speakers are found in India. In addition to being the national language of Pakistan, Urdu is one of the Schedule VIII languages of the Indian democracy, the state official language of Jammu and Kashmir, and the second official language of UP, Bihar, and Andhra Pradesh in India. It is recognized that Urdu, Hindi, and Hindustani share a common grammatical system. Urdu in its colloquial form may therefore be considered the lingua franca of one of the largest speech communities in the world. Urdu is regarded as a pluricentric language that shows different linguistic features.

Origin and Development

Historically, Urdu has developed in a language contact situation over a long period from 1100 A.D. or earlier. After the Muslim invasion of India, it emerged as a speech variety in communication among Muslim rulers, traders, mystics, and the local population. The early form of Urdu developed out of the literary language Sauraseni Apabraṃsa, which was in a state of transition and developing as a New Indo-Aryan language. It had a wide dialect base that included Braj Bhasha, Haryanvi or Bangaru, eastern Panjabi, and other dialects spoken in the region surrounding Delhi. Khaṛi Boli was present as one of the elements in the formative period of Urdu and it gradually became stronger with its development. By 1800, Khaṛi Boli could be considered as the basic source of Urdu. During the period of development, from 1100 to 1800 A.D., Urdu was known by several different names, including Hindwi, Dehalvi, Hindustani, Zaban-e-Urdu, Dakhini or Old Urdu, and Rekhta. The first use of the language name Urdu was made in a couplet in 1776 by the poet Mashafi (1750–1824). However, the use of Urdu, referring to camp, court, or city (Zaban-e-Urdu or Zaban-e-Urdu-e-Shahi or Zaban-e-Urdu-e-Mualla), had been in use from 1560.

Specimens of Hindwi in the early formative period are found scattered in the Nath Panthi literature, early Sufis of North India, Amir Khusro, Nanak, Kabir, Baba Farid, and other poets. Amir Khusro (1236–1324) shows a distinct earlier form of Urdu, or Hindwi as he calls it. However, there is no evidence that the language was in continuous use from 1200 to 1650 except *Bikat Kahani* by Afzal, which appeared 300 years after Amir Khusro's writings. It is therefore not possible to reconstruct a continuous history of the development of Urdu (Chatterji, 1960; Khan, 1958). Insha Allah Khan Insha's *Darya-e-Latafat* ('The river of elegance,' 1807) presents an early linguistic study of the dialects of Delhi and Lucknow.

The emergent variety Hindwi traveled in the south with the Muslim rulers of the Delhi Sultanate (1211–1504) along with the Muslim armies, traders, Sufis, preachers, and other people. It flourished as a literary language in the Decean kingdoms of Golkunda and Bijapur. It was popularly known as Dakhini or Hindwi or Dehalvi. Dakhini has been claimed as

Dakhini Hindi, Dakhini Urdu, or Old Urdu. It shows some linguistic features that are characteristic of its contact with local languages of the South. However, the origin and development of Dakhini has been traced to Haryanvi, Panjabi, Braj Bhasha, and Khaṛi Boli.

During the Mughal period, Persian was the official language of the court. The elite and noblemen spoke and wrote Persian. The Mughal emperors from Akbar onward spoke an early form of Hindustani at home (Chatterji, 1960). Both the Hindus and the Mughal rulers accepted Braj Bhasha as a literary language. Akbar's courtier, Khan Khanan Rahim, wrote in Braj Bhasha, and even Akbar attempted to write some verses in it. Hindustani or Khari Boli did not develop as a literary language in the north until Wali from Aurangabad arrived in Delhi at the end of the 17th century. Wali demonstrated that Hindustani with a scattering of Persian words could be used to write great poetry. The language used by Wali is known as Rekhta, which means 'scattered,' and implies that Hindustani or Urdu had not been 'Persianized.' The Delhi school of poetry came into existence around Wali during 1700–1720.

By the end of the 18th century and the beginning of the 19th, Urdu, in its modern form, had taken deep roots. Several factors contributed to the emergence of Urdu in its distinct modern form. First, the Dakhini literature was written in the Perso–Arabic script, which had "fixed the orientation of the language" (Chatterji, 1960). Wali and subsequent poets and writers readily adopted the Perso–Arabic script. It became a symbol of linguistic and cultural identity. Second, conscious efforts were made by stalwarts such as Khan Arzu (1689–1756), Shah Hatim (1699–1781), and Mazhar Janejanan (1700–1781) to weed out the Braj Bhasha or indigenous words from Rekhta and incorporate Arabic and Persian words in it during the middle of the 18th century. The extreme Persianization of Urdu became characteristic of the Lucknow school of poetry, whereas the Delhi school developed its own standard form of Urdu. Third, the use of subjunctive constructions, the continuous tenses with 'raha,' the ergative construction with the postposition 'ne,' and the formation of the present tense with imperfect participles became stable and characteristic. Finally, prose began to be written in the emergent Khaṛi Boli by the end of the 18th century. The establishment of Fort William College at the beginning of the 19th century encouraged the development of two styles of prose that paved the way for the emergence of Hindi and Urdu as distinct standard varieties. The two important earliest works in Urdu prose are the *Bagh-o-Bahar* of Mir Amman (1804) and the *Khirad Afroz* of Hafizuddin Ahmed (1803–1815).

Urdu Language: Identity and Conflict

The 19th century may be considered to be the century of consolidation, expansion, and growth of Urdu language identity and literature, on the one hand, and the spread of Urdu and sociopolitical mobilization, on the other. Several mutually interactive forces played a catalytic role in this regard. A synoptic view of some of these factors reflects this. First, after the early prose produced at Fort William College, Urdu literature developed rapidly. All genres of literature, including novel, short story, drama, different forms of prose, and journalistic forms developed and made distinctive achievements. Urdu poets throughout the 19th century flourished, and Urdu entered the modern period with Hali (1837–1914) and Akbar Allahabadi (1846–1921) as well as many others. Muhammad Hussain Azad (1830–1910), in *Ab-e hayat* (1880), provided the first systematic account of the achievements of Urdu poetry, constructing a literary history, a canon, and the theory of poetry. Second, the establishment of several educational institutions, including Delhi College, Anjuman-e-Punjab, and Mohammedan Anglo–Oriental College, played multiple roles in enriching Urdu literature with translations from English as well as original writings in different disciplines. This trend spread the use of Urdu language and literature and contributed to the development of linguistic, literary, and cultural identity. Third, Urdu language and literature gained in momentum when it replaced Persian in 1837. It was used as an official court language along with English in the British-ruled provinces in North India. It gave rise to what is popularly known as the Hindi movement. Between 1868 and 1900, the Hindus of the northwestern provinces fought against Urdu through pamphlets and memoranda. They argued that the Perso–Arabic script was alien to India, that it was unintelligible to common people, and that Hindi written in the Devanagari should be made an official language. As a result of the agitation, in 1881 Hindi replaced Urdu in Devanagari script as the official language of the neighboring province of Bihar. This paved the way for the hardening of cultural-communal attitudes among the speakers of Urdu and Hindi, the divergence of Hindi and Urdu, and the formation of different linguistic identities. This can be seen in the exclusion of Hindu poets and the Hindu community in constructing the history of Urdu literature, on the one hand, and the switching of Hindu writers from Urdu to Hindi on the other (Faruqi, 2001). Prem Chand's switch from Urdu to Hindi was not merely an individual, personal choice but also was intricately involved with interrelated linguistic, political, and economic developments. This

process reached its culmination with the complete identification of Urdu with Muslims in the second quarter of the 20th century.

The conflict between Urdu and Hindi was aggravated by the end of the 19th century and in the second quarter of the 20th century. Two factors played a significant role in this process. First, this period saw the development of voluntary language associations such as Nagari Pracharini Sabha, formed in 1893, Hindi Sahitya Sammelan, founded in 1910, and Anjuman-Taraqqi-e-Urdu, formed in 1903. These associations promoted the cause of Hindi and Urdu, divided the loyalties of Hindi–Urdu speakers and writers, strengthened the linguistic divisions, and consolidated separate identities. Second, the Hindi–Urdu conflict and identities were reinforced by the development of both Hindu and Muslim revivalism and communal antagonism in the context of the Western culture, on the one hand, and the growth of the independence movement, on the other. As a consequence, the political mobilization of the masses contributed to the congruence of symbols of linguistic, cultural, and linguistic identities with the process of nationalism and nation formation. Das Gupta (1971: 57) points out that the identification of nationalism, linguistic, and religions solidarity was "more integral and pervasive" in the case of Muslims as compared to that of the Hindus. Ultimately, the partition of India led to the development of Urdu language and literature in India and Pakistan along different lines. This resulted in two linguistic and literary consequences. First, both the Hindi and Urdu speakers gave up Hindustani on ideological grounds. Although Hindi speakers identified Hindustani with Urdu, the Urdu speakers considered it another form of Hindi. Second, both the Hindi and Urdu speakers lost sensitivity and ability to appreciate the literature in a language other than their own.

Linguistic Description

It is generally recognized that Hindi and Urdu share a common grammatical system. They differ mainly in their writing systems, in their lexicon borrowed from Sanskrit or Persian and Arabic resources, and the minor aspects of syntax. Thus, at the phonological level, Urdu has a subset of phonemes (f x š z ž γ q) because of Perso–Arabic words, whereas Hindi has acquired ṇ ṇ š ṣ from Sanskrit words. Kelkar (1968: 80) points out that "it is highly unlikely that H ṣ ṇ i on the one hand, U q ʔ z x on the other will coexist in the same idiolect." Similarly, Urdu has acquired some other distinctive phonological features. Khan (1978: 10–11) points out that Urdu speakers invariably break up consonant clusters in VCC structure in words of Sanskrit origin, but they pronounce the structure correctly in the Persian and Arabic words. This is partly because of cultural influence of Perso-Arabic vocabulary, and partly because of the educational background of speakers. This refers to the phenomenon of *Schwa* deletion having a wider scope in phonological analysis. Narang and Becker (1971) show that a group of derived nouns and adjectives of Perso–Arabic origin represent an exception to the *Schwa* deletion rule. In short, the distinctive phonological features of Urdu are mainly due to Perso-Arabic words. However, it is generally not specified whether these features are characteristic of written or spoken style or both, or educated or uneducated speakers of Urdu.

The issue of lexical borrowing raises different problems at the lexical or semantic level. Borrowed words may be considered in terms of word classes such as nouns, adjectives, adverbs, compound verb formatives, and so on. For instance, Hindi and Urdu show a clear difference in compound verbs consisting of noun + verb or adjective + verb sequences such as U šurū karnā, istēmāl karnā and H ārambh karnā and prayōg karnā. It is essential to highlight some important issues that are not discussed in the analysis of lexical differences between Hindi and Urdu. First, the studies of distinctive lexicon are based on restricted data as evident from Mobbs (1981) and van Olphen (1989). The implications of the nature and scope of lexical differences between Urdu and Hindi can be understood only on the basis of a large representative sample of both spoken and written varieties belonging to different forms of literature. The corpus of three million words, each in Urdu and Hindi, available with the Central Institute of Indian Languages, Mysore, offers challenging opportunities for a wide range of linguistic studies. Second, it is necessary to recognize that the choice of a word of Persian or Arabic origin does not necessarily imply a choice in favor of Urdu. Similarly, the use of words of Sanskrit origin does not imply Hindi. In other words, both Perso–Arabic and Sanskrit words may have been assimilated and become part of the primary system of Hindustani and thus constitute an integral feature of both Hindi and Urdu. Finally, it is essential to move beyond individual lexical items and bring out the implications of borrowed words in collocations and in reflecting different cultural meanings, values, and history. In other words, it is essential to explore to what extent different sets of Perso–Arabic or Sanskrit vocabulary individually as well as in different collocations contribute to the construction of different conceptualization of entities, events, and situations, and different worldview, at the semantic level. Prem Chand's switch from Urdu to Hindi clearly shows how he found Sanskrit vocabulary congenial to the

themes of his works and the sociocultural worldview related with them (Trivedi, 1989).

The borrowing of Perso–Arabic words in Urdu creates characteristic linguistic features at the grammatical level. This can be seen in a number of word-forming suffixes and prefixes. The process of compound formation in Persian has contributed to productivity of compounds in Urdu. Similarly, the process of word formation in Urdu depends a great deal on Arabic resources. This is particularly evident in the various derived verbs with their associated participles and verbal nouns along with their word forming affixes and vowel patterns added to the root. In other words, the productive process of word formation characteristic of Urdu at the grammatical level shows a deep impact of Perso–Arabic resources. Similarly, the distinctive grammatical features of Urdu can be seen in the use of some prepositions, negative particles, formation of noun duals, or plurals in the case of some nouns that are a result of Perso–Arabic influence. The grammatical analysis of Urdu cannot ignore these linguistic devices, as they are extremely productive and provide a distinctive character. However, a number of issues remain to be explored. First, it is essential to explore how deeply these linguistic devices have influenced the structure of Urdu. It will be useful to study whether these features are particularly typical of literary or administrative language, or newspaper texts, or they are also found in everyday Urdu use. Second, it would be relevant to explore the extent to which these linguistic devices support the process of divergence of Urdu from the colloquial Hindustani grammatical system. In this respect, van Olphen (1989) points out that "it is convergence that threatens Urdu in India." By contrast, Hasnain (1995) shows in a small-scale empirical study of Urdu used in mass media and education that innovations in language based on Perso–Arabic resources of word formation have implications for comprehension or intelligibility of language use. In short, whereas language innovations based on Perso–Arabic resources may contribute to divergence of Urdu from the Hindustani grammatical system, the pressure of comprehensibility may check the trend of divergence. The consequences of the dynamics of convergence and divergence will become clear only in the long run.

Codification and Standardization

Language planning agencies and organizations played a significant role in the development and standardization of Urdu. Anjuman Taraqq-e-Hind, established in 1903, has been in the forefront in the development and promotion of Urdu. After the partition of India, the reorganized organization was less militant and more concerned with the promotion and popularization of Urdu among the people. It has 10 branches in different states and eminent leaders, such as Kazi Abdul Gaffar and Zakir Hussain, have played an important role in its growth. It has made a significant contribution for the recognition of Urdu as a second official language in UP and Bihar and for the extension of its use in schools, colleges, and in radio communication. It has been engaged in the organization of celebration of Ghalib (1797–1869), Iqbal (1878–1938), and Prem Chand (1880–1936) days to popularize Urdu and Urdu conventions involving educational, literary, social, cultural, and political societies (Brass, 1975). Another organization, the Deeni Talimi Council, has focused its attention on the contents of textbooks. It works for the preservation of Muslim cultural values and basic tenets of Islam. Jamia Milia Islamia, established in 1920, has become one of the important educational and academic institutions concerned with Urdu education and academic research. The University Grants Commission recognizes it as a 'central university.' It not only gained prestige and respectability in Urdu education and studies but also played a constructive role in support of Urdu by influencing the language policy of the Union Government (Das Gupta, 1970).

In addition to the nongovernmental organizations, the central and state governments have made a significant contribution to the development and standardization of Urdu. The Bureau for the Promotion of Urdu, established by the Government of India in 1969, has done extensive work on the codification and standardization of Urdu. It has produced 100 000 Urdu technical terms for various disciplines of natural sciences, social sciences, and art, published more than 600 books on academic subjects, and compiled Urdu–Urdu and English–Urdu dictionaries, and Urdu encyclopedias. In UP, Bihar, Madhya Pradesh, Maharashtra, and other states, Urdu academies have been working on translation of books from English, publication of standard literary and scholarly works, university level textbooks, and the promotion of Urdu through seminars and conferences. Similar work on the codification and standardization of Urdu has been going on in Pakistan. The evaluation of the extensive work on development, codification, and standardization of Urdu needs to be studied, focusing on the impact of this on language change and development of pluricentric norms in the two countries. This is also relevant from the point of view of divergence of standard Urdu from the colloquial norm and its implications for comprehension by educated speakers of Urdu.

Although the codification and standardization work by both the government and nongovernmental organizations is essential and significant, it is also important to recognize the contribution of the individuals as creative writers, researchers, scholars, educationalists, linguists, and teachers who play a critical role in the stabilization and cultivation of the standard language. It is not possible to mention all the names of Urdu specialists who have made a substantive contribution to research and development of Urdu. It may, however, be mentioned that several eminent scholars and researchers on Urdu have been recognized for their seminal contribution in various fields of studies on Urdu including Urdu script and spelling reform, lexicography, standardization of pronunciation and vocabulary, historiography of Urdu language and literature, and linguistic analysis and description.

Urdu Literature

Literature has been one of the most significant sources of language development and standardization in the case of many developed languages of the world. The history of Urdu shows parallel development of both literature as well as language. Just as Urdu language was formed in communication and social interaction between two cultures in the situation of language contact, Urdu literature shows fusion of two literary and cultural traditions. The Perso–Arabic elements in Urdu language do not merely constitute a superimposed structure but also form an integral aspect of language identity and its literary tradition. They have a rich semantic potential expressive of Islamic tradition and cultural worldview. Similarly, Urdu literature shows a synthesis between Islamic and Indian cultural traditions at literary, aesthetic, and philosophical levels. Narang (1991) maintains that although Urdu literature has been deeply influenced by Persian literature and rich Iranian and Islamic tradition, it has imbibed Indian cultural influences and has emerged as an expression of the composite culture of India. This is evident from the development of various forms and genres of literature during the last 300 years.

Medieval Urdu poetry shows profound influence of Persian literary tradition in its various forms, imagery, and figures of speech, as well as themes and background. The *ghazal* in the medieval poetry has "no local color," lacks personal touches, and appears to have largely a "museum" quality (Sadiq, 1984). However, in the process of development of Urdu literature over the next two centauries, *ghazal* grew beyond erotic themes. Sadiq (1984: 19) points out that "nothing seems to be alien to its genius and it has readily accommodated ethics, metaphysics, philosophy, mysticism, satire, politics, side by side love, which still continues to be its favourite theme." The semiotic analysis of *ghazals* of Ghalib, Iqbal, Faiz, and Firaq Gorakhpuri (1896–1982) brings out the rich potential of the genre of *ghazal*. The same is true of other genres such as *Masnavi*, *Marsiya*, *Qasida*, and so on. *Masnavis* of Mir Hasan (1727–1786) are soaked with Indian imagery (Sadiq, 1984: 16). Srivastava (1992) shows that *Masnawi* as a poetic form has assimilated in its content Puranic legends, Indian folktales, semihistorical events of Indian soil, and so on in the process of its endogenous growth. The popular love lyric *Qawwali* was not only exclusively developed in India but also became an integral part of the secular North Indian music gaining in popularity, as did its indigenous counterparts such as Hindu Kirtan or Bhajan (Narang, 1991). Mushaira (poetic symposia) has become a popular literary convention in India, Pakistan, and other parts of the world.

The modern Urdu literature has many great achievements to its credit. The individual achievements of great poets, writers, and men of letters are difficult to enumerate. However, it would be adequate to mention a few points that are characteristic of the vitality of Urdu literature. First, the development of Urdu literature has kept pace with the trends and tendencies of the time and produced poets and writers belonging to different traditions, movements, and ideologies. Similar to literary traditions in other major Indian languages, it represents a great deal of involvement, sensitivity, and an awareness of contemporary social reality. For instance, the progressive story writers in Urdu, Rajendra Singh Bedi, Manto (1913–1955), Krishan Chander (1914–1977), and Ismat Chugtai (1915–1991), give expression to economic inequality, social exploitation, and male chauvinism as do their counterparts in Hindi. Quarratul-ain-Haider (b. 1928) and Ismat Chugtai in Urdu focus on Indian women and their consciousness as do Manu Bhandari and Krishna Sobti in Hindi. The Sahitya Akademi award to Ismat Chugtai and the Jnanpeeth award to Quarraul-ain-Haider have gained recognition for Urdu literature at the national level.

Second, Urdu literature is not merely restricted to poetry or fiction. It encompasses a wide range of literary criticism, folk literature, children's literature, and scientific literature. In terms of total literary output, Urdu does not lag behind several major Indian languages.

Finally, it is worth emphasizing that several Urdu poets and writers have carried forward the tradition of the synthesis of the Islamic and the Indian cultures.

In this context, Salahuddin Pervez has achieved a great distinction in his novel *Identity Card* for giving expression to the spirit of Islamic thought and its interaction with the Indian spiritual–cultural system and transforming it into a powerful universal humanistic Indo-Islamic ethos. There is a distinct progress in sincere appreciation and creative assimilation of Buddhist thought and its cultural tradition. Both poets and fiction writers discover a rich potential of myths, jataka tales, and Buddhist philosophy. Quarratul-ain-Haider in her masterpiece *Aag Ka Darya* ('The river of fire') makes an imaginative representation of Vedic and Buddhist elements in the spiritual saga of man. Khalilur Rahman Aazmi (d. 1978), one of the pioneers of the new movement in Urdu poetry, presents Gautam as a symbol of perfection. Similarly, Yusuf Zafar, a leading figure of New Poetry in Pakistan, portrays Buddha as an embodiment of love and compassion and a landmark in the spiritual history of mankind.

In short, Urdu literature shows a genuine creative assimilation of the ancient Indian cultural tradition and philosophy in the context of the contemporary problems of mankind in modern age. The standardization and elaboration of the Urdu language shows not only its communicative dynamics and expressive potential but also the loyalty and identity of its speakers. Thus, the Urdu language and literature have gained recognition because of their vitality and achievements and spread at the international level.

The national language of Uruguay and the language of most of its population (estimated at 3 094 000 in 1990) is Spanish, but a Spanish that when spoken may differ quite widely from the standard Castilian of the Iberian Peninsula. Within Uruguay the Department of Rocha is something of an exception, in that Spanish spoken there is the closest to that of the Peninsula, a fact that is accounted for by the Castilian origin of its settlers and its relative isolation from the capital.

The areas in which Uruguayan Spanish differs from standard Castilian include phonology (the pronunciation of-*ll*-in the same way as *y*) and syntax (e.g., the use of the *voseo americano* – the widespread use of *vos* instead of the standard second person singular *tú*, with a modified set of verb endings). The more salient differences, however, are in lexis. A subcategorization of the vocabulary items involved includes the following (some of which are shared by other Latin American varieties of Spanish):

a. Amerindian words. Many Guaraní Indian words are found in the vocabulary of Uruguay in the lexical fields of local flora and fauna: for example, *caraguatá* 'kind of thistle', *ñandú* 'rhea bird'.
b. Archaisms. Some words that are considered archaic in Spain are still current in Uruguay and elsewhere in Latin America: for example, *pollera* 'skirt'.
c. Africanisms. These are found in Uruguayan Spanish because of the slave trade (the first cargo of black slaves arrived in Montevideo in 1756 and slavery in Uruguay was abolished in 1842) and because of Uruguay's proximity to Brazil. Examples are *malambo* 'dance', *macú* 'big drum'.
d. *Lunfardo*. *Lunfardo*, which has been compared with Spanish *caló*, French *argot*, and English *thieves' cant*, was originally the coded language of a very clearly delineated socioprofessional class, those who frequented bars and brothels, and who spent time in prison. It includes such words as *cana* 'prison' and *yeta* 'bad luck'. Based on Spanish, it drew on the language of different immigrant groups (Neapolitans, Genoese), the language used by sailors and dockworkers, and the language of criminals. In certain contexts it may be classified as a kind of professional jargon; see, for instance, the number of different *lunfardo* words used by pickpockets: for example, *grillo* 'side pocket of trousers', *sotal* 'inside pocket of jacket'. *Lunfardo* spread throughout society and became part of popular speech, both rural and urban. It is a major element in the lyrics of the immensely popular tango, which has also caused its dissemination.

In the region where Uruguay borders on Brazil the linguistic situation is considerably influenced by the presence of Portuguese. There are different degrees of penetration, ranging from virtual bilingualism in the towns that stand on the frontier to the existence of several frontier dialects (*brasilero, carimbão, basaño, portuñol*). These may have a Portuguese or a Spanish base; verbs from one language may be conjugated according to the rules of the other; and words may have a Spanish root and a Portuguese ending or vice versa. These dialects are sometimes unintelligible to both Uruguayans and Brazilians.

In schools in Uruguay the most widely taught foreign language is English, partly because many Uruguayans emigrate to English-speaking countries (United States, Australia), but French is also taught. The literacy rate in 1990 for people over 10 years of age was approximately 95%.

The national language of Uruguay and the language of most of its population (estimated at 3 094 000 in 1990) is Spanish, but a Spanish that when spoken may differ quite widely from the standard Castilian of the Iberian Peninsula. Within Uruguay the Department of Rocha is something of an exception, in that Spanish spoken there is the closest to that of the Peninsula, a fact that is accounted for by the Castilian origin of its settlers and its relative isolation from the capital.

The areas in which Uruguayan Spanish differs from standard Castilian include phonology (the pronunciation of-*ll*-in the same way as *y*) and syntax (e.g., the use of the *voseo americano* – the widespread use of *vos* instead of the standard second person singular *tú*, with a modified set of verb endings). The more salient differences, however, are in lexis. A subcategorization of the vocabulary items involved includes the following (some of which are shared by other Latin American varieties of Spanish):

a. Amerindian words. Many Guaraní Indian words are found in the vocabulary of Uruguay in the lexical fields of local flora and fauna: for example, *caraguatá* 'kind of thistle', *ñandú* 'rhea bird'.
b. Archaisms. Some words that are considered archaic in Spain are still current in Uruguay and elsewhere in Latin America: for example, *pollera* 'skirt'.
c. Africanisms. These are found in Uruguayan Spanish because of the slave trade (the first cargo of black slaves arrived in Montevideo in 1756 and slavery in Uruguay was abolished in 1842) and because of Uruguay's proximity to Brazil. Examples are *malambo* 'dance', *macú* 'big drum'.
d. *Lunfardo*. *Lunfardo*, which has been compared with Spanish *caló*, French *argot*, and English *thieves' cant*, was originally the coded language of a very clearly delineated socioprofessional class, those who frequented bars and brothels, and who spent time in prison. It includes such words as *cana* 'prison' and *yeta* 'bad luck'. Based on Spanish, it drew on the language of different immigrant groups (Neapolitans, Genoese), the language used by sailors and dockworkers, and the language of criminals. In certain contexts it may be classified as a kind of professional jargon; see, for instance, the number of different *lunfardo* words used by pickpockets: for example, *grillo* 'side pocket of trousers', *sotal* 'inside pocket of jacket'. *Lunfardo* spread throughout society and became part of popular speech, both rural and urban. It is a major element in the lyrics of the immensely popular tango, which has also caused its dissemination.

In the region where Uruguay borders on Brazil the linguistic situation is considerably influenced by the presence of Portuguese. There are different degrees of penetration, ranging from virtual bilingualism in the towns that stand on the frontier to the existence of several frontier dialects (*brasilero, carimbão, basaño, portuñol*). These may have a Portuguese or a Spanish base; verbs from one language may be conjugated according to the rules of the other; and words may have a Spanish root and a Portuguese ending or vice versa. These dialects are sometimes unintelligible to both Uruguayans and Brazilians.

In schools in Uruguay the most widely taught foreign language is English, partly because many Uruguayans emigrate to English-speaking countries (United States, Australia), but French is also taught. The literacy rate in 1990 for people over 10 years of age was approximately 95%.

Use Theories of Meaning

G Martí, ICREA and Universitat de Barcelona, Barcelona, Spain

© 2006 Elsevier Ltd. All rights reserved.

Traditional theories of meaning of the kind proposed by Frege, Russell, and the early Wittgenstein take to heart the idea that language is a system of symbols whose essential role is to **state** or to **represent** the goings on of the world and the mind. From the point of view of a traditional, or representationalist, approach to meaning, the fundamental area of inquiry about language and its significance has to do with the connection between linguistic items and the things they stand for or represent, things or facts. That is why two of the main focal points of traditional theories of meaning are the theory of reference – the exploration of the bond that ties expressions in a language to things in the world – and the theory of propositions – the discussion of the form and the constitution of what is expressed by utterances of sentences and their role in the determination of truth or falsity. So-called use theories of meaning can be best seen as reactions to the fundamental tenets of traditional theories: whereas traditional theories focus on what language represents and how it represents it, use theories search for the key to meaning in actual usage and linguistic practice.

The first strong appeal to use in the theory of meaning appeared in print in 1950, in P. F. Strawson's article 'On Referring.' Strawson's article is meant to be primarily a critical response to the analysis of sentences containing definite descriptions proposed by Bertrand Russell in his seminal paper 'On Denoting.' The merits or demerits of Strawson's specific objections to Russell's theory of descriptions will not be addressed here. The important point for our purposes is rather the positive outlook on meaning that Strawson's remarks suggest. In criticizing Russell, Strawson (1971: 9) contends that "to talk about the meaning of an expression or sentence [is to talk about] the rules, habits, conventions governing its correct use, on all occasions to refer or to assert". Although rather programmatic in character, Strawson's remarks point towards a conception of the significance of linguistic expressions that departs radically from the Frege–Russell–early Wittgenstein approach for, according to Strawson, neither the things that terms stand for, as Russell and Wittgenstein would have it, nor the conceptual material associated with expressions – the sense – that in turn determines what those expressions stand for, as Frege would have it, constitute appropriate answers to the question 'What is the meaning of X?' On the contrary: "to give the meaning of an expression is to give general directions for its use" (Strawson, 1971: 9).

Traditional theories of meaning, with their emphasis on reference and propositions, leave out of the realm of semantic inquiry a host of expressions whose significance cannot be doubted. For what does 'hello' refer to? What proposition do we express, what fragment of the world do we represent, when we say 'hello'? If we do express a proposition, under which conditions is it true or false? Unlike traditional theories, use theories of meaning would explain the meaning of 'hello' and similar expressions by appeal to the rules and conventions that indicate their appropriate use. But it is not only expressions such as 'hello,' 'ouch,' or 'pardon' that, according to use theorists, are left behind by traditional approaches. J. L. Austin argued that this is so for a class of sentences, which he characterized as 'performative,' that look grammatically like any other subject-predicate or subject-verb-object sentence that we use to represent a fragment of the world, such as 'It is raining' or 'The train is late.' We use the latter to tell the way things are and consequently when we utter them we say something true or something false. Performative utterances, on the other hand, do not state or represent the way things are. When we utter a performative, Austin argues, we certainly say something significant, yet it is neither true nor false. The uses of sentences that Austin is thinking of are utterances of, for instance, 'I name this ship *Queen Elizabeth*,' 'I do [take this man to be my husband],' 'I promise to be at the party,' 'I apologize.' According to Austin what all these sentences have in common is that by uttering one of them we do not report or describe a state of affairs, an event or an action. Uttering one of those sentences is actually **performing** an action. Uttering a performative is a speech act. By saying 'I do,' as Austin (1961: 235) puts it, "I am not reporting on a marriage, I am indulging in it". Because utterances of performatives do not function like statements, the question of truth or falsity does not arise with regard to them. However, there are, Austin points out, ways in which performatives can succeed or fail. For instance, if the utterer does not have the authority to give a name to a ship, her utterance of 'I name this ship *Queen Elizabeth*' does not succeed in performing the intended action. For an utterance of a performative to be satisfactory some felicity conditions must be in place.

It is tempting to think that Austin is highlighting a phenomenon circumscribed to a well-delimited class

of utterances, and that for the vast majority of natural language sentences the traditional representational picture applies smoothly. That is not so: what Austin is proposing is not just a specific treatment of a peculiar phenomenon but rather a different conception of meaningfulness. On Austin's view, statements, as much as performatives, are essentially speech acts and are therefore subject to similar conditions of adequacy and success. Suppose we utter a statement such as 'John's children are all very polite' and John has no children. According to Austin, the situation as regards that statement parallels a performative utterance such as 'I promise I will sell you this piece of land' when the piece of land in question does not exist. In the latter case we would say that the sale is void; and in the former case we should say that the statement is void also. Both performatives and statements are subject to the question 'Is it in order?' If the answer is negative, the performance fails. And if the answer is positive, then both performatives and statements are subject to further questions of felicity. Those questions may take different forms depending on the type of speech act: if it is a warning, the question is whether it was justified; if it is a piece of advice, the question is whether it was sound; if it is a statement, the question is whether it was true; in every case, although in different forms, those questions "can only be decided by considering how the content ... is related in some way to fact ... we do require to assess at least a great many performative utterances in a general dimension of correspondence with fact" (Austin, 1961: 250). In this way Austin (1961: 251) takes statements "off their pedestal" and offers a uniform picture of meaning that appeals essentially to our usage of expressions to do things.

Among use theorists we cannot forget Ludwig Wittgenstein, the coiner of the motto 'meaning is use.' In the first part of the *Philosophical Investigations*, completed in 1945 although not published until 1953, Wittgenstein reacts strongly against the traditional conception of meaning. In fact, Wittgenstein is reacting against his own earlier views presented in the *Tractatus Logico-Philosophicus*. Wittgenstein's account of meaning in the *Tractatus*, with its characterization of the proposition as a picture of a fragment of the world, is the paramount example of a traditional representationalist approach. In the *Investigations*, by contrast, Wittgenstein rejects the explanatory project of Frege and Russell: neither the Fregean senses that are supposed to determine the objects expressions refer to, nor the things that on Russell's (and the *Tractatus*'s) approach are directly and conventionally associated with signs, give life and significance to language: only its use gives meaning to a sign.

To understand the kind of practice we engage in when we use a language as members of a speakers' community, Wittgenstein appeals to the metaphor of playing a game. For Wittgenstein, learning a language, like playing tennis, consists in becoming competent at a rule-governed practice. It does not consist in explicitly learning the rules, having them, so to speak, written in one's mind; being able to play tennis, or being able to speak and understand a language consists in being proficient at doing something according to the rules.

Different use-oriented approaches to meaning criticize the traditionalist stance for disregarding the fact that language is a tool that we use to do things, that speaking and understanding a language is a matter of engaging in a practice, and that, consequently, the key to meaning is to be found in the way language users employ language. But how radical the departure from the traditional stance is depends on how the motto 'meaning is use' is interpreted. On the one hand it may be interpreted as a claim about what gives expressions the meaning they have. The appeal to use is then a reminder that languages are social institutions and that it is by virtue of usage that expressions are connected to their meanings. From this point of view, it is not inappropriate to say, for instance, that by virtue of its use, the word 'dog' means a certain concept or that its meaning consists in naming a species. So interpreted, the claim that meaning is use is fundamentally presemantic, it is not a claim about what constitutes the meaning of expressions. So conceived, use theories of meaning are not opposed in essence to traditional theories, although by stressing the meaning-conferring role of use they expand the horizons of the traditional stance, for they make room in semantic theory for expressions whose meaning cannot be cashed out in terms of what and how they represent objects or states of affairs, and they do not disregard aspects of meaning that are not truth conditional.

A more radical way of interpreting the claim that meaning is use is as a semantic claim, i.e., a claim about what constitutes the meaning of linguistic expressions. From this point of view there is nothing over and above the way an expression is used that can qualify as its meaning. Use is not just what makes an expression have a meaning: it is **all there is** to meaning. Some varieties of deflationism take this stance. Thus, for instance, in Horwich (1998: 6) we read: "The meaning property of a word reduces [to] ... the property that every use of the word is explained in terms of the fact that we accept certain specified sentences containing it."

The radical interpretation of the claim that meaning is use faces a number of objections. Here I will

focus on only two general challenges (for discussion, see Horwich, 1998). First, it may be argued that the idea that use determines the meaning of an expression puts the cart before the horse. Intuitively there is a distinction to be drawn between correct or incorrect usage. No matter how pervasive the use of 'irregardless' is, it is an incorrect expression. The very idea of incorrect, but extended, use seems to entail that it is because expressions do have a meaning, over and above the way in which they are used, that we can talk about correct or incorrect usage. Meaning determines (correct) use and not vice versa, so it seems that the claim that meaning is constituted by use has difficulties accounting for the normative aspect of meaning.

Second, the idea that all there is to the meaning of an expression is its use does not leave room for what appears to be a legitimate possibility: a speaker may be competent in the use of an expression, she may know the situations in which it is appropriate to use it and how to react to uses of it, and yet she may not know the meaning of the expression in question. The possibility is, in fact, less far fetched than it appears. Consider the case of Helen Keller: blind and deaf from an early age, she explains in her autobiography how she and her family had developed a rather good system of symbols to communicate their needs and wishes: when she wanted bread, she made a sign, when she wanted ice cream, she made another sign. Her mother had ways to tell Helen what she needed, and Helen would go and get it for her: Helen had mastered the use of a system of symbols. Nevertheless, when she was seven her teacher, Miss Sullivan, once spelled on Helen's hand the sign for water while Helen felt water with her other hand, and that was the moment that she describes as "learning the key to all language." What could she possibly have discovered that she didn't know before? It surely was not how to use the sign 'water' but rather, and quite simply, that 'water' stands for water. Now, it may be argued that learning that 'water' can be used to refer to water is indeed learning something new about the use of 'water.' But then it would appear that even from the point of view of use theories of meaning we need to be sensitive to the fact that expressions represent things and that it is the relation between words and things that makes it possible for us to talk about the world.

Use versus Mention

C Spencer, Howard University, Washington, DC, USA

© 2006 Elsevier Ltd. All rights reserved.

Generally, the distinction between using something and mentioning it is completely straightforward. For instance, there is all the difference in the world between mentioning, or talking about, a lawn mower, and using it to mow the lawn. Yet the distinction can engender some confusion when it comes to mental and linguistic representations, and this is what philosophers and linguists have in mind when they talk about the use/mention distinction. The distinction between mentioning a word, picture, or mental representation, and using it to communicate or entertain a thought is best illustrated by example. Sentence (1) uses the word 'Boston,' and sentence (2) mentions it.

(1) Fred is from Boston.
(2) 'Boston' has two syllables.

Philosophers customarily put a word (or complex expression) inside quotation marks, to form its 'quote

focus on only two general challenges (for discussion, see Horwich, 1998). First, it may be argued that the idea that use determines the meaning of an expression puts the cart before the horse. Intuitively there is a distinction to be drawn between correct or incorrect usage. No matter how pervasive the use of 'irregardless' is, it is an incorrect expression. The very idea of incorrect, but extended, use seems to entail that it is because expressions do have a meaning, over and above the way in which they are used, that we can talk about correct or incorrect usage. Use versus Mention

C Spencer, Howard University, Washington, DC, USA

© 2006 Elsevier Ltd. All rights reserved.

Generally, the distinction between using something and mentioning it is completely straightforward. For instance, there is all the difference in the world between mentioning, or talking about, a lawn mower, and using it to mow the lawn. Yet the distinction can engender some confusion when it comes to mental and linguistic representations, and this is what philosophers and linguists have in mind when they talk about the use/mention distinction. The distinction between mentioning a word, picture, or mental representation, and using it to communicate or entertain a thought is best illustrated by example. Sentence (1) uses the word 'Boston,' and sentence (2) mentions it.

(1) Fred is from Boston.
(2) 'Boston' has two syllables.

Philosophers customarily put a word (or complex expression) inside quotation marks, to form its 'quote

name,' if they want to mention it instead of using it, as in (2). Linguists, in contrast, typically use italics, labeled bracketing trees, or a phonetic alphabet to mention an expression, as in (3a–c).

(3a) *Boston* has two syllables.
(3b) [$_{NP}$ Boston] has two syllables.
(3c) bɐs tən has two syllables.

An advantage of the philosopher's convention is that we may easily form the quote name of a quote name simply by enclosing the quote name itself in quotation marks, as in (4):

(4) '"Boston"' is the name of a word, not a city.

We can also mention an expression without using any of these devices, as in (5) and (6).

(5) The first line of Gray's Elegy states a proposition.
(6) Samuel Clemens's pen name is derived from a riverboat driver's call.

Example (5) uses an expression, 'the first line of Gray's Elegy,' to mention the linguistic expression it denotes, namely, 'The curfew tolls the knell of parting day.' Similarly in (6), the expression 'Samuel Clemens's pen name' is used to mention another linguistic expression, namely 'Mark Twain.'

When we talk more systematically about a particular language, as we do in describing its syntax or semantics, we observe the related distinction between object language and metalanguage. The object language is the language under discussion, and the metalanguage is the language we use to talk about the object language. In some cases, the object language and the metalanguage are different languages, as in (7), but the object language and the metalanguage can be the very same, as in (8).

(7) 'Le chien est sur la chaise' is true if and only if the dog is on the chair.
(8) 'The dog is on the chair' is true if and only if the dog is on the chair.

Sentences (7) and (8) mention sentences of the object language (enclosed within quotation marks). The metalanguage, in both cases English, is the language used to state the truth condition of sentences in the object language.

Sentences that mention themselves, such as (9), can give rise to paradox.

(9) This sentence is false.

Sentence (9) appears to have the paradoxical property of expressing a truth if and only if it expresses a falsehood. Many sentences that mention themselves are innocent in this respect, such as (10):

(10) This sentence contains five words.

The paradox only arises for sentences that self-ascribe semantic properties such as truth or falsehood. A central project of a theory of truth is to resolve this paradox.

So far, the use/mention distinction seems easy to keep straight: How could someone confuse the name 'Boston' with the New England city itself? Yet philosophers sometimes charge one another with confusing use and mention of linguistic expressions. Such confusion typically results in mere obscurity, as it does in this passage from Leibniz, as translated by C. I. Lewis.

> Two terms are the same if one can be substituted for the other without altering the truth of any statement. If we have A and B and A enters into some true proposition, and the substitution of B for A wherever it appears, results in a new proposition which is likewise true, and if this can be done for every such proposition, then A and B are said to be the same; and conversely, if A and B are the same, then they can be substituted for one another as I have said (Lewis, 1960: 291).

Richard Cartwright has suggested that the apparent use/mention confusion here makes it difficult to see exactly what Leibniz intended to say in this passage (Cartwright, 1971: 119). Perhaps Leibniz meant that A and B are the same if and only if **their names** can be intersubstituted into any statement without altering the truth value of the proposition that the statement expresses. If this was what he meant, then in some places he should have **mentioned** the names of A and B rather than **using** them, as he in fact did.

In other cases, however, use/mention confusions may ground substantive philosophical mistakes. One such mistake is the familiar confusion of objects with our ideas of them. This mistake arises particularly for philosophically problematic entities such as the number three and Beethoven's Ninth Symphony. It is obvious that they are not concrete objects, but less obvious what else they could be. Since we clearly have ideas of these objects, some have suggested that we identify the objects themselves with our ideas of them. Cursory reflection reveals that this suggestion cannot be correct, since these entities have properties that ideas could not have. Ideas, for instance, cannot be the cube root of 27 or played frequently by the Berlin Philharmonic. Plausibly, what lies behind this suggestion that objects like these are really ideas in our heads is a confusion of our mental representations of these objects with the objects themselves. Like the confusion of the word 'Boston' with the

city of Boston, this is a straightforward confusion of use with mention.

Uslar, Petr Karlovich (1816–1875)

O Thomason, University of Georgia, Athens, GA, USA

© 2006 Elsevier Ltd. All rights reserved.

Petr Karlovich Uslar was born September 1, 1816 in Kurovo, near Tver', Russia. Uslar was a baron, a linguist, an ethnographer, and a pioneering researcher of Northern Caucasian languages. He was Corresponding Member of the Russian Academy of Science in the Historical–Philological Department (1868). Having received the education of a military engineer (1836), Uslar began his military service in the Caucasus. He became a member of the Caucasian Department of the Imperial Russian Geographical Society (1851) and was directed to compose a work about the history of the Caucasus (1858). Uslar began to study the Caucasian languages, believing them to be a significant source of information about Caucasian history.

Studying languages through communication and interaction with native speakers, Uslar became one of the founders of the field of linguistics in Russia. Having devised his own methods of descriptive language analysis, Uslar gave detailed descriptions of Abkhaz, Avar, Chechen, Dargwa, Lak, Lezgi, Svan, Tabassaran, Ubykh, and other Caucasian languages. In a period of linguistic history when there was a lack of generally accepted linguistic terminology and a shortage of investigations of the non-Indo-European languages, Uslar's works presented a rather clear and objective structure of the described languages. Acknowledging the advantages of the Georgian alphabet, Uslar created an alphabet for many Caucasian languages on the basis of the Russian alphabet. He was motivated in his choice by the existence of close and steady interconnections between the Russian nation and communities of the Caucasus. The phoneme systems of the Caucasian languages given by Uslar were precise (with the exception of the Tabassaran phoneme system) and corresponded to the standards of modern phonology even though the notion of 'phoneme' did not exist at that time. Uslar was also one of the creators of the concept of 'passiveness of ergative constructions,' according to which a transitive verb in an ergative construction was equivalent to a verb in the passive voice. Uslar's theory was not without error, because he identified ergative and instrumental constructions and considered a specific construction of Caucasian languages to be a type of an Indo-European construction.

Uslar was also concerned with problems of education, literacy, and the history of the Caucasian people. Thus, he helped to introduce new methods of teaching reading and writing in schools. Uslar stressed that it was essential and much easier for Caucasian people to learn reading and writing (using the Russian alphabet) in their native language first and only after that to begin the study of Russian grammar.

After Uslar's death, all his grammar books (with the exception of the unfinished Tabassaran grammar book, which was first published more than 100 years after his death) were published in the series *Etnografiia Kavkaza: Iazykoznaniie* as *Abxazskii iazyk* (1887–1896), *Chechenskii iazyk* (1888), *Avarskii iazyk* (1889), *Lakskii iazyk* (1890), *Xiurkilinskii iazyk* (1892), and *Kiurinskii iazyk* (1896). Some of the monographs were supplied with articles and letters written by Uslar. All of these works were enriched with samples of folklore, proverbs, sayings, fairy tales, and fables. Each one also had a short introduction into the culture, geography, and history of a given language and a dictionary of a given language in translation from and into Russian.

He was motivated in his choice by the existence of close and steady interconnections between the Russian nation and communities of the Caucasus. The phoneme systems of the Caucasian languages given by Uslar were precise (with the exception of the Tabassaran phoneme system) and corresponded to the standards of modern phonology even though the notion of 'phoneme' did not exist at that time. Uslar was also one of the creators of the concept of 'passiveness of ergative constructions,' according to which a transitive verb in an ergative construction was equivalent to a verb in the passive voice. Uslar's theory was not without error, because he identified ergative and instrumental constructions and considered a specific construction of Caucasian languages to be a type of an Indo-European construction.

Uslar was also concerned with problems of education, literacy, and the history of the Caucasian people. Thus, he helped to introduce new methods of teaching reading and writing in schools. Uslar stressed that it was essential and much easier for Caucasian people to learn reading and writing (using the Russian alphabet) in their native language first and only after that to begin the study of Russian grammar.

After Uslar's death, all his grammar books (with the exception of the unfinished Tabassaran grammar book, which was first published more than 100 years after his death) were published in the series *Etnografiia Kavkaza: Iazykoznaniie* as *Abxazskii iazyk* (1887–1896), *Chechenskii iazyk* (1888), *Avarskii iazyk* (1889), *Lakskii iazyk* (1890), *Xiurkilinskii iazyk* (1892), and *Kiurinskii iazyk* (1896). Some of the monographs were supplied with articles and letters written by Uslar. All of these works were enriched with samples of folklore, proverbs, sayings, fairy tales, and fables. Each one also had a short introduction into the culture, geography, and history of a given language and a dictionary of a given language in translation from and into Russian.

Uto-Aztecan Languages

C Fowler, University of Nevada, Reno, Nevada

© 2006 Elsevier Ltd. All rights reserved.

Uto-Aztecan is a large family of indigenous languages whose descendants are distributed from Oregon in the north to El Salvador in the south, with the heaviest concentrations of contemporary speakers in northern and central Mexico. Today over 45 extant and extinct languages are recognized as part of the family, with some of the extant languages represented by 50 or fewer speakers and others by well over 100 000 (Campbell, 1997; Ethnologue, 2004). In times past, speakers of these languages included peoples displaying the full range of socioeconomic adaptations, from small extended families who lived by hunting and gathering to clans of small village farmers to intensive agriculturalists organized into vast empires. Today, in many communities in the United States, public education and culture change have reduced the number of speakers to dangerously low levels, and language extinction appears inevitable. For others, concerted efforts at language salvage and revitalization that are currently underway may prolong or actually reverse the decline. For several of the more remote and robust languages of Mexico the picture is brighter and there appears to be less danger of significant language loss in the immediate future.

The languages within the Uto-Aztecan family are divided into three more or less contiguous geographic clusters across their broad range. The names for each cluster and views as to their internal relationships have changed through time and are still subject to some debate. The units are generally referred to as (1) Shoshonean or Northern Uto-Aztecan, which includes several branches and languages concentrated in the Great Basin and southern California in the United States; (2) Sonoran, which includes the languages of southern Arizona in the United States and of Sonora, Chihuahua, and Durango in northwest Mexico; and (3) Aztecan or Nahuatl, with languages widespread in central Mexico and outliers in El Salvador. The Sonoran and Aztecan languages are often subsumed under the term Southern Uto-Aztecan, either as a geographic reference to contrast them with the languages of the north or in recognition of a genetic relationship. The languages within each of the clusters and the branches with which they are affiliated are given in **Table 1**.

Records and studies of Uto-Aztecan languages extend back to the time of the Spanish conquest of Mexico with the compilations of Fray Bernardo de Sahagun from 1540 to 1560 on Classical Aztec or Nahuatl, as well as by other early pioneers. Documentation of most of the northern languages did not begin until exploration and colonization of the western United States in the first decades of the 19th century. As explorers, military expeditions, traders, and missionaries began to compile vocabularies of western U.S. and northern Mexican languages, the work on genetic classifications of them began in earnest. Initial compilations by Albert Gallatin in the 1830s and 1840s, Johann Carl Buschmann in the 1850s, and Albert Gatschet in the 1870s, among others, led to the inclusion in the family of most of the languages and branches recognized at present. Most controversial was the linking of Nahuatl to the Sonoran and ultimately Shoshonean languages,

Uto-Aztecan is a large family of indigenous languages whose descendants are distributed from Oregon in the north to El Salvador in the south, with the heaviest concentrations of contemporary speakers in northern and central Mexico. Today over 45 extant and extinct languages are recognized as part of the family, with some of the extant languages represented by 50 or fewer speakers and others by well over 100 000 (Campbell, 1997; Ethnologue, 2004). In times past, speakers of these languages included peoples displaying the full range of socioeconomic adaptations, from small extended families who lived by hunting and gathering to clans of small village farmers to intensive agriculturalists organized into vast empires. Today, in many communities in the United States, public education and culture change have reduced the number of speakers to dangerously low levels, and language extinction appears inevitable. For others, concerted efforts at language salvage and revitalization that are currently underway may prolong or actually reverse the decline. For several of the more remote and robust languages of Mexico the picture is brighter and there appears to be less danger of significant language loss in the immediate future.

The languages within the Uto-Aztecan family are divided into three more or less contiguous geographic clusters across their broad range. The names for each cluster and views as to their internal relationships have changed through time and are still subject to some debate. The units are generally referred to as (1) Shoshonean or Northern Uto-Aztecan, which includes several branches and languages concentrated in the Great Basin and southern California in the United States; (2) Sonoran, which includes the languages of southern Arizona in the United States and of Sonora, Chihuahua, and Durango in northwest Mexico; and (3) Aztecan or Nahuatl, with languages widespread in central Mexico and outliers in El Salvador. The Sonoran and Aztecan languages are often subsumed under the term Southern Uto-Aztecan, either as a geographic reference to contrast them with the languages of the north or in recognition of a genetic relationship. The languages within each of the clusters and the branches with which they are affiliated are given in Table 1.

Records and studies of Uto-Aztecan languages extend back to the time of the Spanish conquest of Mexico with the compilations of Fray Bernardo de Sahagun from 1540 to 1560 on Classical Aztec or Nahuatl, as well as by other early pioneers. Documentation of most of the northern languages did not begin until exploration and colonization of the western United States in the first decades of the 19th century. As explorers, military expeditions, traders, and missionaries began to compile vocabularies of western U.S. and northern Mexican languages, the work on genetic classifications of them began in earnest. Initial compilations by Albert Gallatin in the 1830s and 1840s, Johann Carl Buschmann in the 1850s, and Albert Gatschet in the 1870s, among others, led to the inclusion in the family of most of the languages and branches recognized at present. Most controversial was the linking of Nahuatl to the Sonoran and ultimately Shoshonean languages,

Table 1 Uto-Aztecan languages

Northern Uto-Aztecan
Numic:
Western [2 languages = Mono (Monache, Owens Valley Paiute) and Northern Paiute (including Bannock)]
Central [3 languages = Panamint (Timbisha), Shoshone (Western, Northern, Eastern, Gosiute) and Comanache]
Southern [2 languages = Kawaiisu and Ute (Northern and Southern Ute, Southern Paiute, Chemehuevi)]
Takic:
Serrano-Gabrieliño [3 languages = Serrano (Vanyume), Kitanemuk, *Gabrieliño (Fernandeño)
Cupan [3 languages = Cahuilla, Cupeño, Luiseño (Juaneño)]
*Tataviam (?)
Tubatulabal
Hopi
Southern Uto-Aztecan
Tepiman:
Upper Piman [1 language = (Pima, Tohono O'odham, Nevome)]
Lower Piman [1 language = (Mountain, Yepachi, Yecora-Maycoba)]
Northern Tepehuan
Southern Tepehuan [1–3 languages = (Southern Tepehuan, Tepecano)]
Taracahitan:
Tarahumaran [2–7 languages = Tarahumara (Western, Northern, Central, Southern, Ariseachi, Summit) and Guarijio (Upland, Lowland)]
Opatan [2 languages = Opata and Eudeve]
Cahitan [1–2 languages = Yaqui and Mayo]
Corachol:
Cora [1–2 languages (Cora, Santa Teresa Cora)]
Huichol
Aztecan:
*Pochutla
General Aztec (4–28 languages/dialects = Pipil, Nahuatl (Mexicano, Aztec, Tetelcingo, Zacapoaxtla, etc.)

After Campbell, 1997; Goddard, 1996; Ethnologue, 2004; does not include all extinct* languages.

proposed by Bushmann and accepted by Gatschet in 1878, but rejected by John Wesley Powell in his classification of 1891. Daniel Brinton in his classification the same year accepted the linkage and is credited with naming the family, choosing a northern language (Ute) and a southern one (Aztec) to represent the unity (Goddard, 1996; Lamb, 1964). However, not until Edward Sapir (1913–1914) provided the first systematic study of sound correspondences and lexical reconstructions within the family by comparing Southern Paiute with Nahuatl was the overall relationship considered to be demonstrated. Since that time, work has concentrated on better understanding internal and external relationships for the family, and on the basic description and documentation of the individual languages (Goddard, 1996; Lamb, 1964).

A link between the Uto-Aztecan language family and the Tanoan languages of the U.S. Southwest and thus ultimately to Kiowa of the U.S. Plains was first suggested by Sapir in his 1929 macro-classification of North American Indian languages. This grouping was referred to by him as Aztec-Tanoan, and later given the position of a phylum or superstock. Benjamin Lee Whorf and George Traeger provided sound correspondences and reconstructions to show the Tanoan linkage, although they initially rejected the inclusion of Kiowa. The Kiowa-Tanoan linkage was confirmed in the late 1950s and early 1960s (Goddard, 1996: 313, 317), but the Aztec-Tanoan combination has not fared as well. Suggestions of this and yet more remote relationships for Uto-Aztecan languages, all of which appear doubtful, are reviewed by Campbell (1997).

The internal relationships of some of the Uto-Aztecan branches and sub-branches are still debated. The combinations of languages that make up the northernmost branch, Numic, found in the Great Basin of the United States, are solid. Two languages, Hopi of northern Arizona and Tubatulabal (Tübatulabal) of southern Sierran California, are understood to be independent branches. Early extinctions and thus lack of data for some of the languages of the Takic branch of southern California make internal relationships difficult to determine with certainty, particularly the position of Garbrialiño and Tataviam (Campbell, 1997: 135). Powell and A. L. Kroeber suggested that these four branches were related to each other by more than geography, and referred to them all as Shoshonean (Lamb, 1964). Miller (1983, 1984), based on a review of cognate sets and comparisons of sound systems, rejected this relationship as genetic, preferring to view the four as independent branches of the family. Others accept the unity of these four

branches, citing shared innovations in the sound systems and aspects of morphology as evidence (Goddard, 1996; Campbell, 1997; Heath, 1977, 1985; Manaster Ramer, 1992).

Internal diversity within the remaining branches of the family is also debated, with some arguing for and others against various subgroupings. Again, the problem of language extinctions and thus lack of data enters into the discussion (see Campbell, 1997: 133–135 for details), with Miller (1983) remarking that relationships make the family resemble less a tree than a vine that has been severely pruned! Names for the remaining branches also differ, but there is general agreement on Tepiman (Pimic), Taracahitan (Taracahitic), Corachol (Cora-Huichol), and Aztecan (Goddard, 1996; Campbell, 1997). The position of a fifth branch, Tubar, is likewise debated, with some placing it within Taracahitan (Kaufman, 1974). Some keep Tarahumara and Cahitan as independent branches (Ethnologue, 2004), and others include these with the first three named as a genetic subunit called Sonoran. Sonoran has a long history going back to Buschmann, with the most recent evidence being presented by Hale (1964). The unity of Southern Uto-Aztecan, including Sonoran and Aztecan, is less controversial than the proposal for Northern Uto-Atecan (Campbell, 1997; Goddard, 1996; Heath, 1977, 1985; Manaster Ramer, 1992; Miller, 1983, 1984), although there is still some argument over the position of Aztecan as either having independent status within that unit or being more closely related to Corachol (Campbell and Langacker, 1978).

Most of the languages of Uto-Aztecan, with the exception of those that went extinct early, have been reasonably well studied, beginning with the work on Southern Paiute grammar, texts, and a dictionary by Sapir in 1910 (Sapir, 1930–1931). Most recent in a long line of descriptive works is the publication of the massive *Hopi dictionary* (Hill *et al.*, 1998), representing the largest compilation to date for a Native American language. In between, sufficient descriptive works have been published by numerous authors to provide the data for reconstruction of the basic sound system of the proto-language, as well as an outline of some of its grammatical features, and a partial lexicon.

The Proto-Uto-Aztecan sound system is considered by most to contain a single series of voiceless stops (p, t, c, k, k^w, ʔ), -s, h, two nasals [m, n (or ŋ)], a lateral (l), plus w, y, and possibly r, along with a five vowel system (i, a, ɨ, o, u) plus vowel length (following Campbell, 1997). There is some disagreement as to the identity and directionality of the n, ŋŋ, and l: **n > *ŋ and **l > *n, particularly in selected environments in Northern Uto-Aztecan, or **ŋ > *n and **n > * l in selected environments in Southern Uto-Aztecan (see Campbell, 1997: 136–137) for discussion). The status of **r is likewise not clear, with some suggesting that it is one reflex of **t (Campbell, 1997: 137). Additional work with the cognate sets initially compiled by Miller (1967, 1988) may clarify the matter. The basic sound system has come down to the daughter languages with various alternations, with not all paths particularly clear.

Work on comparative grammar dates to the 1960s and 1970s (Heath, 1978; Langacker, 1977; Steele, 1979; Voegelin, Voegelin and Hale, 1962). Based on these studies, the proto-language is considered to have had several features, including an 'absolutive' noun suffix, used to mark a noun that is neither possessed nor carries another postposition; an auxiliary that contained a complex of modal, pronominal, and tense elements; and various pronomial elements on the verb that marked a reflexive object (Steele, 1979: 444–448). The proto-language is also considered to be a verb final language, with a much richer verb morphology than noun morphology.

The broad distribution of Uto-Aztecan languages has spurred several investigations into the linguistic prehistory of the family, with archaeologists, anthropologists, and linguists making contributions through the years. Comparative lexical work has suggested homelands for Proto-Uto-Aztecan in various locations within its present range, and various features, including agriculture, for its earliest speakers (Fowler, 1983; Hill, 2001, 2003). The language family has thus been fertile ground for testing many hypotheses from historical and theoretical linguistics to anthropological concerns. Today, the expertise of many Uto-Aztecan specialists, especially in the United States, is also being given to Native communities in partnerships addressing language salvage and revitalization in order to preserve these significant languages for speakers in the future.

Location and Speakers

Uyghur (uyɣur tili, uyɣurča), formerly called Eastern Turki, is spoken in the Chinese Xinjiang Autonomous Region (Eastern Turkistan). It belongs to the Southeastern (Uyghur, Uyghur-Karluk, or Chaghatay) branch of the Turkic language family.

At least 10 million native speakers of Uyghur live in Xinjiang. This region borders Kirghizstan and Tajikistan in the west; Kazakhstan in the northwest; Mongolia in the north and northeast; the Russian Federation in the north; Afghanistan, Jammu, and Kashmir in the southwest; Tibet in the southeast; and the Chinese provinces Gansu and Qinghai in the east. Other languages spoken in Xinjiang include Chinese, Kazakh, and Kirghiz. The speakers of Uyghur predominantly live in the oases north of the Tarim river, on the southern slopes of Tienshan, and on the northern slopes of Kunlun in the southern Taklamakan desert up to the region west of the Lop desert. About half a million speakers of Uyghur live in eastern Kazakhstan, Kyrgyzstan,

Uyghur (uyɣur tili, uyɣurča), formerly called Eastern Turki, is spoken in the Chinese Xinjiang Autonomous Region (Eastern Turkistan). It belongs to the Southeastern (Uyghur, Uyghur-Karluk, or Chaghatay) branch of the Turkic language family.

At least 10 million native speakers of Uyghur live in Xinjiang. This region borders Kirghizstan and Tajikistan in the west; Kazakhstan in the northwest; Mongolia in the north and northeast; the Russian Federation in the north; Afghanistan, Jammu, and Kashmir in the southwest; Tibet in the southeast; and the Chinese provinces Gansu and Qinghai in the east. Other languages spoken in Xinjiang include Chinese, Kazakh, and Kirghiz. The speakers of Uyghur predominantly live in the oases north of the Tarim river, on the southern slopes of Tienshan, and on the northern slopes of Kunlun in the southern Taklamakan desert up to the region west of the Lop desert. About half a million speakers of Uyghur live in eastern Kazakhstan, Kyrgyzstan,

Uzbekistan, Tajikistan, Turkmenistan, Afghanistan, and Mongolia.

The status of Uyghur in Xinjiang is stable. Official documents are issued in both Uyghur and Chinese. Though education in Uyghur is possible up to the university level, Chinese, the dominant language, is necessary for higher education. The Uyghurs make strong efforts to maintain and cultivate their language. In Kazakhstan, a few Uyghur schools exist, and there is a certain publishing activity in Uyghur.

Origin and History

The Old Uyghurs, living near the Selenga River on the territory of today's Mongolia, were vassals of the eastern Türk confederation. They defeated the Türk in 744 and created an empire that extended from Lake Baikal to the Altay Mountains. From here, they expanded their realm to Gansu in the east, and incorporated the Tarim basin and the Ferghana valley. The Uyghurs entertained close contacts with China, adopted Manicheanism, and acted as the religion's protective power.

In 840, the Uyghurs were defeated by the Kirghiz, another Turkic-speaking tribal confederation. Most Uyghurs and many of their subjects fled southward. One group settled in the Ordos region of northern China and assimilated with Chinese and Mongols. The Uyghurs who settled in the Gansu corridor of western China, establishing contact with Tibetans and Mongols, are the ancestors of today's Yellow Uyghurs. The largest group fled to the Tarim basin. In Turfan, the southwesternmost possession of their steppe empire, the Uyghurs established the kingdom of Kocho, which expanded rapidly over large parts of the Tarim basin. It existed until the Mongol invasion in the 13th century, and as a semiautonomous state for some time afterwards. A rich sedentary culture emerged, in which the Uyghur language was used for a comprehensive literary production.

Various Turkic groups had settled in this region from the 6th century on, particularly in the colonies of the Türk empire. The western Tarim basin was predominantly populated by Karluks. Large parts of the area had thus been Turkicized long before the Uyghurs settled here. The Turkic-speaking groups eventually absorbed the indigenous non-Turkic population of Indo-European origin, i.e., speakers of Soghdian (Sogdian) and Tokharian. The southern oases north of Kunlun were mostly populated by Saka speakers. Their region, which had its center in Khotan, essentially remained untouched by Turkicization up to the Mongol period.

The Old Uyghur culture was finally extinguished through the advancement of Islam. The first Islamic Turkic state in the east, the Karakhanid empire, was established in the 10th century, with Kashgar developing into the leading Islamic center in the east. Later on, the oasis states of the Tarim basin were controlled by Karakitay, Mongols, Junggars, and various local rulers. In the 20th century, Eastern Turkistan became a bone of contention in conflicts between Russia, China, and Britain.

Related Languages and Language Contacts

Uyghur is closely related to Uzbek. Modern Uyghur partly goes back to Old Uyghur, which is close to the language of the Orkhon inscriptions of the Türk dynasty. It is not a direct continuation of Old Uyghur, but differs considerably from it as a result of interaction with Indo-European varieties such as Soghdian and Tokharian, and other Turkic varieties. The Turkic varieties of Eastern Turkistan, a major crossroad of Central Asia, have been in contact with numerous other languages. A strong substratum influence has been exerted by speakers of Indo-European shifting to Turkic. Uyghurs had early contacts with Mongols, and later contacts with Kirghiz and Kazakhs. Elements of Persian and Arabic origin were spread by merchants and religious teachers along the Silk Road. Contacts with Russian began in the early 20th century. The long contacts with Chinese have been particularly important. The presence of Chinese speakers in Xinjiang has increased considerably since the 1950s.

The Written Language

Old Uyghur was a highly developed literary language, attested by rich historical materials, mostly of a religious – predominantly Buddhist, but also Manichaean and Nestorian Christian – nature. A rich treasure of Old Uyghur documents, written in various scripts, has been preserved, the last ones dating back to the 15th century. In the Islamic era, Eastern Turkistan was the birthplace of the literary language known as Karakhanid ('Khakani' Turkic), created in the 11th century in Kashgar, the cultural center of the Karakhanid state. Kashgar also became the basis of the eastern variety of the transregional literary language Chaghatay, which developed from the 15th century on in the Timurid realm. Modern written Uyghur is the last stage in this literary tradition.

In 1922, an assembly in Tashkent decided to adopt the historical term 'Uyghur' for speakers of Eastern Turki in Russian Turkistan. The designation was officially accepted in Xinjiang in 1934. Standard Uyghur, the official local language of Xinjiang, was originally

based on varieties spoken in the Ili region, mainly on Soviet territory. The basis of the current standard language are the dialects of Ghulja and Ürümchi. Since 1954, the Language and Script Work Committee (Til-yėziq xizmiti komiteti) is responsible for its norms. The current standard pronunciation was determined in 1987 and slightly revised in 1997.

Modern Uyghur was first written with Arabic script. A Cyrillic script was introduced in 1957 but soon replaced by the Roman-based 'new script' (*yėngi yėziq*), based on the Chinese pinyin system. Since this experiment was unsuccessful, the Arabic-based 'old script' (*kona yėziq*) was revived in 1983. The return to it has made written communication with other Turkic-speaking groups more difficult. For Uyghur varieties of the Soviet Union, Arabic script was used up to 1930, then a Roman-based alphabet was used, and, from 1947 on, a Cyrillic script, which is still used in Kazakhstan, Kyrgyzstan, and Uzbekistan.

Distinctive Features

Uyghur exhibits most linguistic features typical of the Turkic family (*see* **Turkic Languages**). It is an agglutinative language with suffixing morphology, sound harmony, and a head-final constituent order. In the following, only a few distinctive features will be dealt with. In the notation of suffixes, capital letters indicate phonetic variation, e.g., *A* = *a/e*, *G* = *ɣ/g*, *K* = *q/k*. Segment within round brackets occur after consonant-final stems only. Hyphens are used here to indicate morpheme boundaries.

Phonology

Uyghur displays many features that are lacking or uncommon in other Turkic languages. The back vowel *ï* is missing in many environments where it is normally found in Turkic, e.g., *yil* 'year.' It is present in the neighborhood of back velars, e.g., *qïz* 'girl' (written *qiz*). The Arabic-based script does not distinguish the vowels *i* and *ï*, though it otherwise provides diacritic signs to designate vowels in an unambiguous way. The typical Turkic frontness-backness and rounded-unrounded harmony is preserved. The latter is relatively weak, many suffixes lacking variants with rounded vowels.

Certain vowel changes and phonological irregularities, in particular regressive assimilations, can be interpreted as Indo-European substratum phenomena. Unaccented nonhigh vowels are raised in open syllables, i.e., *a*, *e*, *ė* > *i*, *o* > *u*, *ö* > *ü*, e.g., *bali-lar* 'children' (*bala* 'child'), *yürüg-üm* [heart-POSS.1.SG] 'my heart' (*yürek* 'heart'). Words of Arabic and Persian origin are not subject to this rule. Two rules of regressive assimilation may be due to contact with Iranian. First, *a* and *e* in open first syllables are raised to *ė* under the influence of *i* or *ï* of the following syllable, e.g., *ėt-im* [horse-POSS.1.SG] 'my horse' (*at* 'horse') or 'my meat' (*et* 'meat'). Second, *a* and *e* in open first syllables are rounded under the influence of *u* or *ü* in the following syllable, e.g., *tömür* 'iron' < *temür*.

Finally *-G* is preserved in monosyllabic words, e.g., *taɣ* 'mountain,' but it is mostly changed to *-K* in nonfirst syllables, e.g., *taɣ-lïq* [mountain-DER] 'mountainous.' Initial *ž-* occurring before high vowels corresponds to *y-* in many other Turkic languages, e.g., *yil* 'year' (Turkish *yıl*). The consonants *r* and *l* are often deleted, particularly before obstruents, e.g., *qa[r]* 'snow,' *qa[r]ga* 'crow,' *bo[l]sa* [be(come)-COND.3.SG] 'if it is.' Loanwords are restructured according to native phonotactical rules. Thus, *f* is mostly replaced by *p*, e.g., *pikir* 'idea' (<*fikr*). Nonpermissible consonant clusters are broken up by means of epenthetic/prothetic vowels or consonant deletion, e.g., *xalïq* 'people' (<*xalq*), *iradiyo* 'radio,' *dos* 'friend' (< *dost*).

Grammar

The ablative suffix is *-Din*, as in Old Uyghur, whereas most Turkic languages exhibit *-Dan*, e.g., *öy-din* [house-ABL] 'from the house.' Uyghur has lost, as Chaghatay already had, the 'pronominal *n*,' which occurs, in most Turkic languages, in third person possessive suffixes before case suffixes, e.g., *öy-i-ge* [house-POSS.3.SG-DAT] 'to her/his house' (cf. Turkish *ev-in-e* [house-POSS.3.SG-DAT]). The polite form of the second person plural pronoun is *si-ler* [you-PL]. There is a general present tense marker going back to **-a tur-ur* (converb suffix + 'stands'), e.g., *oqu-y-du* [read-CONV-3.SG] 'reads, will read,' and a more focal present marker going back to **-p yat-a tur-ur* (converb + 'lie' + converb + 'stands'), e.g., *oqu-wati-du* [read-FOCAL.PRES-3.SG] 'is reading.' Evidentiality is expressed with the copulas *ėken/ėmiš* and the past suffix *-(i)p-tu*. The marker *-gan-di* expresses presumption. More than 20 auxiliary verbs are used in postverb constructions to express manner of action.

Lexicon

Uyghur displays numerous words of Arabic and Persian origin. Many words for abstract concepts are inherited from the Karakhanid-Chaghatay literary tradition. Though this influence has now decreased, one-fifth of the vocabulary is still of Arabic-Persian origin. A large part of the modern technical and administrative vocabulary has been copied from

Russian. The lexical influence of Chinese has become increasingly stronger, and many Chinese neologisms have been copied. In the 1960s, the use of Chinese scientific terminology was obligatory. There is now a tendency to replace Chinese words with products of Turkic word formation, loan translations, and internationalisms copied from Russian.

Dialects

The classification of Uyghur dialects is still controversial. A northern group includes dialects spoken north and east of the Tienshan mountains and immediately south of them. It comprises the westernmost dialects of Kashgar and Yarkent, the more central dialects of Aqsu and Kucha, and the eastern dialects of Turfan and Qumul. The Kashgar-Yarkent dialect is strongly influenced by varieties of Western Turkistan. The Turfan dialect is of special interest, since it seems to stand in a direct historic relationship with Old Uyghur. A particular variety is Taranchi, spoken in the Ili valley by groups that emigrated from Eastern Turkistan at the end of the 18th century. This dialect, which is close to Uzbek, served as the basis of written Uyghur in Russian Turkistan. It is still spoken by Uyghurs in Kazakhstan, Kyrgyzstan, Uzbekistan, etc. A southern group comprises the Khotan dialects. A third group consists of the now nearly extinct Lopnur dialect, which was spoken the eastern Tarim basin and displayed Kirghiz and Mongolian influences. The Khoton (or Busurman 'Muslim') dialect is spoken in the region between the lakes Ubsu-nur and Chirgis-Nur in western Mongolia. The Eynu variety, spoken at various places in southwestern Xinjiang, combines an Uyghur morphosyntax with a special vocabulary of non-Turkic – partly Iranian and partly unknown – origin. Its speakers, all adult men, use it as a secret language to make their conversations unintelligible to outsiders. Salar and Yellow Uyghur were formerly considered dialects of Uyghur. Salar is of Oghuz Turkic origin, whereas Yellow Uyghur is the continuation of an Old Uyghur dialect.

Location and Speakers

Uzbek (*ozbek tili*, *ozbekcha*) belongs, like modern Uyghur, to the southeastern (Uyghur, Uyghur-Karluk, or Chaghatay) branch of the Turkic language family. It is spoken in various dialects in Western Turkistan, primarily in the Republic of Uzbekistan (*Ozbekiston Respublikasi*), which occupies the major part of Transoxiana and has common borders with Afghanistan, Kazakhstan, Kyrgyzstan, Tajikistan, and Turkmenistan. The Uzbek-speaking areas are concentrated in the the lower Zerafshan and upper Syrdarya valleys and in the Ferghana valley, west and northwest of western Tienshan. Though the Uzbeks make up 80% of the population of the republic, Uzbek is spoken by less than 75%, i.e., about 19.8 million people. Other languages of Uzbekistan include Russian and Tajik. The latter is mainly spoken in the oases of Bukhara and Samarkand and in the Ferghana valley. Russian is mainly spoken in the capital,

Russian. The lexical influence of Chinese has become increasingly stronger, and many Chinese neologisms have been copied. In the 1960s, the use of Chinese scientific terminology was obligatory. There is now a tendency to replace Chinese words with products of Turkic word formation, loan translations, and internationalisms copied from Russian.

Location and Speakers

Uzbek (*ozbek tili*, *ozbekcha*) belongs, like modern Uyghur, to the southeastern (Uyghur, Uyghur-Karluk, or Chaghatay) branch of the Turkic language family. It is spoken in various dialects in Western Turkistan, primarily in the Republic of Uzbekistan (*Ozbekiston Respublikasi*), which occupies the major part of Transoxiana and has common borders with Afghanistan, Kazakhstan, Kyrgyzstan, Tajikistan, and Turkmenistan. The Uzbek-speaking areas are concentrated in the the lower Zerafshan and upper Syrdarya valleys and in the Ferghana valley, west and northwest of western Tienshan. Though the Uzbeks make up 80% of the population of the republic, Uzbek is spoken by less than 75%, i.e., about 19.8 million people. Other languages of Uzbekistan include Russian and Tajik. The latter is mainly spoken in the oases of Bukhara and Samarkand and in the Ferghana valley. Russian is mainly spoken in the capital,

Tashkent. Karakalpakistan, which comprises the northwestern part of Uzbekistan, is an autonomous republic with a special status and a language of the Kazakh type. Karakalpaks make up 2% of the population. Many Karakalpaks use Uzbek as a second language. Uzbek is also spoken in parts of Tajikistan (1.2 million speakers), northern Afghanistan (1.5 million), Kyrgyzstan (600 000), Kazakhstan (350 000), Turkmenistan (360 000), and China (Xinjiang) (15 000). The total number of speakers amounts to about 24 million people.

Uzbek–Russian bilingualism is widespread in Uzbekistan, and Russian has a strong position. Uzbek is, however, one of the most firmly established Turkic languages, the second after Turkish in terms of cultural importance. It has been subject to systematic language planning and cultivation. Post-Soviet Uzbek is in a transitional period of dynamic developments. In general, the status of the Russian language has declined. In the first post-Soviet years, Russian was still defined as the medium of 'crossnational communication' in Uzbekistan. Later, it lost this role and its status as a compulsory subject in Uzbek education. However, the goal of enforcing obligatory use of the indigenous languages in public functions within a few years' time has proved unrealistic.

Origin and History

The historical background of the current linguistic situation is highly complex. In what is now Uzbekistan, varieties of southeastern Turkic have been spoken for a millennium, both by nomadic groups and by a sedentary population in close contact with Iranian-speaking groups. An intensive Iranian–Turkic bilingualism developed in Transoxiana and Ferghana. Sizeable Iranian-speaking groups eventually shifted to Turkic. The Uzbek conquest brought in a different element (the original Uzbeks spoke a Kipchak language of the Kazakh type). After the fall of the Golden Horde, the Uzbeks left the Kipchak territory in the Ponto-Caspian area, seized the power in Transoxiana in about 1500, overthrew the Chaghatay empire, and established the khanates of Khiva and Bukhara. The language of these politically dominant groups was gradually absorbed by varieties of southeastern Turkic ('de-Kipchakization'). Different degrees of maintenance of Kipchak elements and of Iranicization mirror the transition from nomadic to sedentary life. Modern Uzbek is based on the language of the old sedentary Turkic population but displays a few Kipchak features. The original Kipchak varieties have gradually vanished with the abandonment of the nomadic lifestyle. Some remnants of them are found in northern and northwestern Uzbekistan. Russia conquered Uzbekistan in the late 19th century. In the 1920s, Soviet Turkistan was split into a number of socialist republics, and an Uzbek republic was set up in 1924.

Related Languages and Language Contacts

Uzbek is most closely related to modern Uyghur, with which it shares important features. The oldest Turkic population of the area had close relations to speakers of Iranian. The predecessor of Uzbek was strongly influenced by Sogdian and, after the Muslim conquest, New Persian. Long-standing intensive contacts with East Persian have led to copying of numerous features in phonology, morphology, vocabulary, and syntax. There are many striking structural similarities between Uzbek and Tajik. These influences, along with later Kipchak Turkic and Russian influences, have given Uzbek a highly composite character. Uzbek–Tajik bilingualism is still alive in some areas, e.g., in and around Samarkand and Bukhara. An increasing Uzbek influence on Tajik may be observed. Kirghiz–Uzbek bilingualism is found in Kirghiz towns bordering on the Uzbek Ferghana valley.

The Written Language

Persian was for a long time the prestigious language of administration and higher culture in Transoxiana. Its importance later decreased in favor of Chaghatay, the Persian-influenced literary language of the Chaghatay empire cultivated in Samarkand, Bukhara, Tashkent, Ferghana, and other centers. From the 18th century on, Chaghatay developed further through successive modernization and adaptation to regional spoken varieties. The 'Sart' literary language, used until 1920, consisted of Chaghatay with certain modern regional elements. After the Russian conquest of the region, Uzbek was established as the standard language. It was first based on northern dialects, and later, after 1937, on the southern dialects of Tashkent and Ferghana. Modern standard Uzbek is the common 'roof' of highly different varieties.

Uzbek was first, as Chaghatay, written in Arabic script. A Roman-based script was introduced in 1929 and revised in 1934. In 1937, the orthography was simplified. Due to this reform, Uzbek texts became less easily intelligible to readers in neighboring Turkic areas. The old role of Uzbek as a transregional language was thus drastically restricted. A Cyrillic-based script was introduced in 1940 and 1941 and was later modified. The transition to a Roman-based alphabet was enacted by law in 1993. The new script system

was revised in 1995. It is based on the American Standard Code for Information Interchange (ASCII) and dispenses with diacritic signs. The new system preserves the principles of the Cyrillic-based system. It essentially represents a transliteration of the Cyrillic spelling and is thus very different from the Roman-based system of the 1930s.

Distinctive Features

Uzbek exhibits most linguistic features typical of the Turkic family (*see* **Turkic Languages**). It is an agglutinative language with suffixing morphology, sound harmony, and a head-final constituent order. In the following discussions, only a few distinctive features will be dealt with. In the notation of suffixes, capital letters indicate phonetic variation, e.g., A = a/e, G = γ/g, K = q/k. Hyphens are used to indicate morpheme boundaries.

Phonology

The phonetic realizations of the vowels vary greatly. The standard orthography is very vague about the actual pronunciation. With the revision of the Roman-based script in 1934, the vowel signs were reduced to six. When, in 1937, the strongly Iranicized Tashkent dialect was chosen as the norm for the standard language, the signs for *ö*, *ü*, and *ï* disappeared, and the front vowel *æ* was written with the letter 'a.' These principles have been maintained in the new Roman-based system. Modern spelling thus applies a system of six vowel signs, identical with the system used for Tajik. It does not reflect the fact that the distinctions between back and front vowels have been largely preserved.

Standard Uzbek is claimed to have, as a result of Iranian influence, the six vowel phonemes *a*, *e*, *å*, *i*, *o*, and *u*. This analysis is mirrored in the orthography. The sign 'a' stands for a front *æ*, but also for a backed 'a' when adjacent to back-velar or uvular consonants. The higher vowel *e* occurs in first syllables, e.g., *er* 'husband' and *keræk* 'necessary.' A labialized *å* occurs in first syllables, e.g., *ålti* 'six' and *åra* 'interval,' confusingly enough written with the letter 'o.' Similarly, the letter 'i' stands for a front *i*, but also for a backed *ï* when adjacent to back-velar or uvular consonants, e.g., *yaxšï* 'good.' High, unrounded vowels are often reduced or lost in closed syllables before certain consonants, e.g., [b^{i}r] 'one.' The vowels *ȯ* and *u̇* (with a somewhat retracted pronunciation) occur instead of Common Turkic *ö* and *ü*, e.g., *ȯlik* 'dead' and *tu̇n* 'night.' The distinctions *o* vs. *ȯ* and *u* vs. *u̇* are not reflected in the script. Thus, pairs such as *bol-* 'become' vs. *bȯl-* 'divide' and *uč* 'end' vs. *u̇č* 'three' are homographic in modern spelling.

Due to Iranian influence, the manifestations of sound harmony are less straightforward than in most other Turkic languages. There are disturbances of the vowel harmony in most urban dialects, whereas the northern dialects have preserved vowel harmony. Suffixes are very often invariable and their vowels are not assimilating to the frontness–backness or the roundedness–unroundedness of the preceding vowel.

The notation of consonants in the new orthography follows the principles of the Cyrillic-based script. For example, 'ch' represents *č*, 'sh' represents *š*, and 'j' represents *ǰ*. The back velars *q* and *γ* are represented by *q* and *g'*; the front velars *k* and *g* are represented by 'k' and 'g'. As in Uyghur, final *-G* has mostly changed to *-K* in nonfirst-syllable positions, e.g., *sariq* 'yellow' and *tirik* 'alive' (cf. Turkish *sarı* and *diri*).

The realizations of suffixes are highly regular. Uzbek displays less consonant assimilations of suffix-initial *n*, *d*, and *l* than most neighboring languages do. The standard spelling is basically morphological and normally does not indicate vowel harmony or consonant assimilations. In loanwords, high epenthetic vowels are inserted to dissolve nonpermissible consonant clusters, e.g., *fik^{i}r* 'thought' (written *fikr*). However, elements of Russian, Arabic, and Persian origin usually reflect the original forms as written in Cyrillic and Arabic script. Assimilations and other adaptations are thus obscured, e.g., *nisbat* 'relation' for [*nispæt*].

Grammar

Uzbek lacks the 'pronominal n' in the declension of nouns with third-person possessive suffixes, e.g., *qol-i-da* [hand-POSS.3.SG-LOC] 'in his/her hand' (Turkish *kol-un-da* [hand-POSS.3.SG-LOC]). The genitive suffix *-niŋ* is mostly pronounced as *-ni*, thus coinciding with the accusative suffix. Like Uyghur, Uzbek has abandoned the old pronominal flexion in favor of nominal flexion, e.g., *sen-gæ* [you-DAT] 'to you' (Turkish *sana* [you-DAT]). The demonstrative pronouns constitute a four-place system with *bu* 'this,' *šu* 'this (in view),' *oša* 'this (in view, more distant),' and *u* 'that.' Lower numerals can assume the suffix *-tæ*, e.g., *ikki-tæ* 'two (pieces).' The suffixes *-åw* and *-ælæ* form collective numerals, e.g., *ikk-åw* 'the two' and *ikk-ælæ-si* [two-COLL-POSS.3.SG] 'both of them.'

The general present-tense marker goes back to converb suffix + 'stands,' e.g., *kel-æ-di* [come-PRES-3.SG] 'comes, will come.' More focal present markers include *-(æ)yæp* and *-(æ)yåtir*, going back to constructions with *yåt-* 'to lie,' e.g., *yåz-yæp-ti* [write-FOCAL.PRES-3.SG] 'is writing (just now)' and *kel-æ-yåtir* [come-FOCAL.PRES-3.SG] 'is coming.' Other focal forms with various nuances can be formed with auxiliary verbs meaning 'to stand,' 'to sit,' or 'to

move,' e.g., *yåz-ib turib-mæn* [write-FOCAL.PRES-1.SG] 'I am writing.' Evidentiality is expressed by the indirective past marker *-(i)bdi* and the indirective copula particles *ekæn/emiš*, e.g., *ayt-ib-di* [say-EV-3.SG] 'obviously said,' *unut-ib-mæn* [forget-EV-1.SG] 'I have obviously forgotten,' and *kæsæl ekæn* [ill COP.EV] 'is obviously ill.' The interrogative forms *-mi-kæn* and *mi-kin* express doubt, e.g., *kel-gæn-mikan?* [come-POSTTERMINAL.PAST INTERROG] 'has (s)he really come?' The postterminal ('past') marker *-gæn* is used as participle and as a finite form, as in most other Turkic languages, corresponding functionally to Turkish *-mIş*, *-(y)An*, and *-DIK*. There is also an intraterminal ('present') participle in *-digæn*. Postverb constructions with converb forms of the lexical verbs plus auxiliary verbs are used to express semantic modifications, including manner of action, e.g. *-æ ber-* 'to do continuously, to keep doing.' The Persian impact on Uzbek syntax is considerable.

Lexicon

The Uzbek vocabulary contains many loans of Arabic–Persian origin, mostly copied from Persian and inherited from the old literary language, Chaghatay. The strong Iranian influence on Uzbek has led to borrowing of word-formation affixes, even prefixes, e.g., *nå-toγri* 'untrue' (*nå-* 'non-' copied from Persian plus Turkic *toγri* 'right, true'). Female gender is expressed in some nouns borrowed from Arabic and Russian, e.g., *šåir-a* [poet-FEM] 'poetess' (*šåir* 'poet') and *student-ka* [student-FEM] 'female student' (*student* 'student'). Most conjunctions are of Arabic–Persian origin.

Dialects

The dialects exhibit different degrees of Iranicization. The northern dialects, spoken in southern Kazakhstan, north of Tashkent, show little Iranian influence. Southern Uzbek includes the dominant urban dialects of Tashkent, Bukhara, Samarkand, etc., which go back to varieties of the settled populations. They have been heavily influenced by East Persian in their vowel system, for example. Moderately Iranicized dialects are spoken east of Tashkent, in the Ferghana valley, representing a successive transition to Uyghur. The rural dialects of the Kipchak type are Kazakh dialects. Oghuz Turkic dialects, improperly called Oghuz Uzbek, are spoken in Khorezm and adjacent areas. Related dialects are also spoken in southern Uzbekistan and in southern Kazakhstan.

Uzbekistan: Language Situation

D W Montgomery, Boston University, Brookline, MA, USA

© 2006 Elsevier Ltd. All rights reserved.

The landlocked Central Asian republic of Uzbekistan shares borders with Kazakhstan on the west and north, with Kyrgyzstan and Tajikistan on the east, and with Afghanistan and Turkmenistan on the south. With about 26 million inhabitants, it is the most populous country of the region. The main language of Uzbekistan is Uzbek (Uzbek, Northern), spoken by about three-quarters of the population, followed by Russian (about 14%), Tajik Tajiki (4%), and several other languages spoken in

neighboring countries, such as Turkmen, Kazakh, and Kirghiz. After having been part of the Soviet Union, Uzbekistan became independent in 1991. As in many Central Asian countries, language policy became important after independence. In particular, Uzbekistan introduced a spelling reform: a Latin-based orthography for Uzbek.

Changes in alphabet are political endeavors that proceed in concert with the creation of linguistic identity. Such has been the case with Uzbekistan and the surrounding countries of Central Asia, whose scripts have undergone changes from Arabic (1923–1929) to Latin (1929–1940) to Cyrillic (1940). Lenin favored Latin because he associated it with modernity; Stalin favored Cyrillic for its ability to unify the Soviet Union. Since independence, however, Uzbekistan has sought to assert its legitimacy of nationhood. One step in this process was September 1993 legislation that dictated a transition of the alphabet used in Uzbekistan from Cyrillic to Latin letters. Although change has been implemented incrementally in the schools, the change was, in theory, to be fully implemented by 2005.

The rationale behind an Uzbek change in alphabet relates to an assertion of national identity along linguistic lines that separate Uzbeks from non-Uzbeks. A Latin alphabet marked a clear distinction from Russia and, at the time of initiation, hinted at a desire for closer relations with Western countries and with Turkey. Economically, arguments for Latin included its being the alphabet of computers and the global economy. In terms of security, a shift to Latin rather than Arabic script (which was discussed as a possible option) afforded some distance from the Arabic-speaking Islamic-extremist threats to the country. And perhaps most significantly, Latinized Uzbek emphasized the geopolitical borders of Uzbekistan, distinguishing it from Kyrgyzstan and Kazakhstan, which use Cyrillic script; Afghanistan, which uses Arabic script; and Tajikistan, which uses both Cyrillic and Arabic letters. (Turkmenistan also adopted a Latin alphabet but remains politically isolated because of the policies of its government.)

In addition to the visual barriers the Latinization of Uzbek creates with its neighbors, it also cuts off future generations from access to the written history of the Uzbek SSR, which used Cyrillic. (This situation has parallels, of course, with Kemalist reforms in Turkey.) Eventually, a history of Uzbekistan will be rewritten in the Latin alphabet, according to 'official' designs, and over time, people will become separated from the written language of those before them.

Uzbeks living outside Uzbekistan, in countries where Latinized Uzbek is not learned, risk losing access to the modern print literature of their homeland. Uzbeks living in Kyrgyzstan, for example, still learn Uzbek in Cyrillic and have difficulty obtaining textbooks because they do not use the Latinized Uzbek schoolbooks.

The printed word gives a fair amount of legitimacy to a nation, and the development of the vernacular is an integral part of nationalism. While alphabet changes do not isolate or prevent groups from verbal communication, such changes do present significant barriers to written communication. These barriers to written communication in turn become barriers to a community's collective memory in addition to impeding the transmission of knowledge and the development of thought to the extent that it is done through a written medium.

Already, Uzbek children have worked their way through the school system learning the Latin script and, unless they study Russian, do not learn the Cyrillic alphabet. Elderly Uzbeks have expressed dissatisfaction with the change in alphabets but often relinquish any protest to their fate of aging. In Uzbekistan today, one sees an increasing amount of Latin script in public places, although many public signs – such as those announcing theater performances or public events – remain in Cyrillic.

V

Vachek, Josef (1909–1996)

T Fögen, Humboldt-Universität Berlin, Berlin, Germany

© 2006 Elsevier Ltd. All rights reserved.

Josef Vachek was born in Prague on March 1, 1909 and died on March 31, 1996. He was one of the most prominent members of the second generation of the Prague School members and one of the most distinguished scholars of English from Czechoslovakia. He studied English and Slavic languages at Charles University in Prague from 1927 to 1932; among his teachers were Vilém Mathesius (1882–1945), Bohumil Trnka (1895–1984), and Miloš Weingart (1890–1939). He became secretary of the Prague Linguistic Circle (PLC) while he was still a student. A draft of his study 'On the phonological interpretation of diphthongs with special consideration of English' was first presented at one of the meetings of the PLC in early 1931 and later turned into a doctoral dissertation, which was submitted in 1932 and subsequently published in German (*Příspěvky k dějinám řeči a literatury anglické* [*Prague Studies in English*] *4,* 1933, 89–172). From 1932 to 1945 he served as teacher of English and Czech at Czechoslovak Commercial College (Československá akademie obchodní) and for the English Grammar School of Prague. In addition, he taught English at Charles University from May 1945 onward. In December 1945 he submitted his Habilitation 'Universal negation in English and Czech' ('Obecný zápor v angličtině a v češtině,' *Příspěvky k dějinám řeči a literatury anglické* [*Prague Studies in English*] *6,* 1947) and became professor at the University of Brno (1947–1961). From 1961 to 1971 he worked for the Institute of Czech (Ústav pro jazyk český) at the Czechoslovak Academy of Sciences in Prague. He was visiting professor at Indiana University in Bloomington (1964) and at Leiden University (1968–69). Beginning in 1971, he held professorships at Comenius University and 17th November University, both in Bratislava. Although he officially retired at the end of February 1976, he continued to work as an external member of staff at the University of Prešov (March 1976–June 1980). Vachek's academic as well as personal memoirs are collected in his 1994 booklet *Vzpomínky českého anglisty* (Reminiscences of a Czech Anglicist), which is at the same time an overview of linguistics, in particular English linguistics, in Czechoslovakia since Vilém Mathesius and the foundation of the Prague Linguistic Circle. To Vachek's pupils belong Jan Firbas, Aleš Svoboda, Josef Hladký, and Libuše Dušková.

His main areas of interest were synchronic and diachronic phonology, syntax, and sociolinguistics, to all of which he frequently applied a contrastive approach, as can be seen in particular from his structural comparison of English and Czech. In phonology he devoted most of his attention to the study of present-day English and Czech, but also to the historical development of their phonological systems. Connected with this was Vachek's research on graphemics and orthography. In syntax he dealt with the structure of universal negation as well as analytical tendencies in present-day English. Another focus in his work was the analysis of the dichotomy between spoken and written language: Although the norm of written language is deduced from that of spoken language, the norm of written language is regarded as neither functionally nor structurally subordinate to the other one; rather, both norms complement one another. He also emphasized that the relation between the spoken and written norms of a language may change considerably in the course of time, and that different languages may exhibit different trends of development in this respect. Finally, Vachek's pedagogical mastery is proven by the fact that during his time as a high-school teacher he produced a number of teaching manuals of Czech and English; for the purposes of academic instruction in English he wrote several university textbooks.

One of Vachek's achievements is to have promoted the ideas of the Prague School by editing readers with translations of seminal articles formerly available only in Czech. He also issued other useful tools for a better understanding of the approach of the Prague School, such as a dictionary, originally published in French in 1960, but now also available in an

updated English translation with supplementary texts (2003).

Vagueness

C Barker, University of California, San Diego, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

Vagueness is the name of a particular kind of uncertainty about the applicability of a predicate. The standard example of a vague predicate is the class of gradable adjectives, including *tall*. If Bill is not quite tall enough to be clearly tall, and not quite short enough to be clearly not tall, then he is a borderline case. The reluctance we feel to assert either that Bill is tall or that Bill is not tall is due to the vagueness inherent in the meaning of the word *tall*.

The Sorities Paradox (Paradox of the Heap)

The tension between small changes and big consequences gives rise to the Sorities Paradox, sometimes known as the Paradox of the Heap (Kamp, 1981; Williamson, 1994). The paradox consists of two main premises. Base premise: Clearly, 1 grain of sand does not qualify as a heap. Inductive premise: Adding a single grain of sand is never sufficient to turn a collection of sand grains that is not a heap into one that is a heap. If we accept both of these premises, then it follows that no matter how many grains of

Vagueness

C Barker, University of California, San Diego, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

Vagueness is the name of a particular kind of uncertainty about the applicability of a predicate. The standard example of a vague predicate is the class of gradable adjectives, including *tall*. If Bill is not quite tall enough to be clearly tall, and not quite short enough to be clearly not tall, then he is a borderline case. The reluctance we feel to assert either that Bill is tall or that Bill is not tall is due to the vagueness inherent in the meaning of the word *tall*.

The Sorities Paradox (Paradox of the Heap)

The tension between small changes and big consequences gives rise to the Sorities Paradox, sometimes known as the Paradox of the Heap (Kamp, 1981; Williamson, 1994). The paradox consists of two main premises. Base premise: Clearly, 1 grain of sand does not qualify as a heap. Inductive premise: Adding a single grain of sand is never sufficient to turn a collection of sand grains that is not a heap into one that is a heap. If we accept both of these premises, then it follows that no matter how many grains of

sand are added to the first grain, the result will never be a heap. Yet eventually, if we add enough sand, there will come a point at which there is a heap, and we have arrived at a paradox. There are many variations. Raffman (1994) imagines a progression of color chips arranged in order from clearly red to clearly yellow. Each color chip in the sequence differs in hue from the next by an amount that is significantly less than the just-perceptible-difference for normal humans under normal circumstances. If so, then by construction, no normal human perceiver can distinguish the hues of any adjacent pair of color chips, which establishes the relevant inductive premise. Yet if the sequence is extended far enough, the endpoints will clearly be in different color categories. This form of the paradox allows consideration of the difference between being red (a question of fact) and seeming red (a question of perception).

Vagueness Is (Almost) Ubiquitous

Much of the research on vagueness studies gradable adjectives such as *tall*, *red*, or *fun*. An adjective is gradable if it undergoes comparative formation *(taller, redder, more fun)* and superlative formation *(tallest, reddest, most fun)*. In any case, vagueness is by no means limited to gradable adjectives. Even among (arguably) nongradable adjectives such as *circular* or *level* (**?more circular*, *?most level*), whether something is sufficiently circular to qualify as circular is a matter of degree, and it takes only a slight effort to coerce a nongradable adjective into a grading context (most famously, *pregnant*, as in *She is more pregnant than I am*, meaning closer to term).

Members of other lexical categories besides adjectives can be vague. Nouns, for instance: whether an object counts as a chair depends on the degree to which it resembles or functions as a chair. Kamp and Partee (1995) discuss connections between psychological research on categorization, prototypicality, concept formation, and linguistic compositionality issues in noun–noun compound formations such as *male nurse, striped apple,* or *stone lion*.

Verbs are equally susceptible to vagueness. Just how tuneless can a vocalization be and still count as singing? Similarly for prepositions (how far exactly do you have to tilt your head before your left eye is below your nose?) and adverbs. In general, any grammatical element whose contribution to truth conditions requires perception, categorization, or judgment of gradient contingent facts – including tense, aspect, and plurality – suffers from an incurable susceptibility to vague uncertainty. In fact, vagueness is so pervasive that it is worth remarking that there are some concepts that have no vagueness whatsoever, such as the mathematical concepts expressed by the noun *integer* or the adjective *prime*. Because a positive integer is prime if and only if it has exactly two distinct factors, any uncertainty concerning whether a number is prime can only come from uncertainty as to what its factors are. Nor is there any relevant sorities series for which any competent and alert speaker would agree to the inductive premise.

A number of linguistic phenomena resemble vagueness in certain ways, including tolerance for small deviations and uncertain applicability, but arguably are distinct from vagueness. For instance, it is unclear how many kinds of birds must be capable of flight in order to justify the claim, *Birds fly,* and it is similarly unclear how strongly disposed to smoke John must be in order to justify the claim, *John smokes*. In these uses, *birds* names a natural kind, and *John smokes* is a characterizing sentence, both of which are usually treated as types of genericity.

In addition, we can say that *Mary arrived at 3 P.M.* even if Mary arrived shortly before or after the stroke of 3. Likewise, we can say that *everyone in the town was asleep* even if a small number of people were awake. Lasersohn (1999) suggested that these are instances of speaking loosely for the sake of pragmatic convenience and argues that they behave differently than genuine vagueness.

Finally, although the prototypical vague predicates are gradable adjectives, Kennedy and McNally (in press) argue that a subtype of gradable adjectives that they call absolute adjectives, including *empty* or *awake*, do not have a context-dependent standard of comparison and therefore are not vague.

Vagueness is often contagious, in the sense that complex expressions built up from vague predicates are often themselves vague as a result. For instance, if *tall* is vague, then the complex predicates *become tall*, *appear tall, meet a tall person*, etc. will also be vague.

Comparatives, Superlatives, Measure Phrases

Interestingly, vagueness is not always contagious. For comparative constructions such as *Bill is taller than Sue*, or *Bill is 5 centimeters taller than Sue*; for superlatives such as *Bill is the tallest person in the room*; and for measure phrases such as *Bill is two meters tall*, there is no entailment that Bill is tall, and there is no vagueness. Because in most languages the comparatives and superlatives are formed by adding suffixes such as *–er* or by means of other independent formatives, there must be some way of incorporating the vague meaning of *tall* into a more complex meanings that exhibit no vagueness. Von Stechow (1984), Klein (1991), and Kennedy (1999) surveyed and

critiqued linguistic theories of comparatives that provide explanations for these facts (*see* **Comparatives: Semantics**).

Vagueness in Context

The evaluation of vague predicates is both context-dependent and context-changing. The context-dependence of vague predicates consists in at least three related but distinguishable factors: reliance on a contextual standard (threshold), reference to a comparison class, and dependence on conversational and other purposes. Reliance on a contextual standard is typical of gradable adjectives. We can say that Bill will count as tall just in case Bill is tall at least to degree d, where d is a threshold for tallness provided by the context. At this point we are setting aside whether the threshold can ever be known precisely or with certainty and considering instead what determines whether the tallness cutoff falls closer to 150 centimeters, 160 centimeters, etc.

For gradable adjectives at least, one important factor affecting the location of the threshold is the set of objects with respect to which the property in question is being judged, the relevant comparison class. What counts as a tall basketball player is different than what counts as a tall kindergarten student, which differs again from what counts as a tall mushroom. A straightforward way of capturing dependence on comparison class is to relativize the denotation of a vague predicate to a class of objects. One argument in favor of this approach is that (for some vague predicates in some situations) the comparison class can optionally be overtly specified with a *for* phrase, as in *He's tall for a basketball player*. When the comparison class argument is not overtly specified, it presumably receives its value from context. As Graff (2000) noted, when comparison classes appear overtly, they must be natural kinds. We can say that someone is tall for a basketball player, because basketball players form a natural kind, but we cannot say that someone is tall for a person in this room, because people do not normally constitute a natural kind by virtue of occupying a particular room. Nevertheless, the objects in a room can affect the location of a vague threshold. For instance, I can tell you, 'Hand me the big book' in a situation in which one book is larger than the others on my desk. Yet I might be unwilling to describe the very same book as big after a number of even larger books have been placed on my desk. Vague predicates not only depend on context for their applicability, but their use also affects the context with respect to which subsequent uses of vague predicates get evaluated. In fact, vague predicates may sometimes be primarily or entirely used to negotiate a suitable standard (Kyburg and Morreau, 2000; Barker, 2002). For instance, if I tell you that Bill is tall, you may come to know something new about Bill. That is a typical descriptive use. But if Bill's height is well known (perhaps he is standing in plain sight), then I can assert that Bill is tall as a way of informing you of what counts as tall in our community (i.e., that henceforth in our discussion that the relevant standard for tallness is less than Bill's maximal degree of height).

Vagueness versus Ambiguity

The difference in applicability of a vague predicate due to context is generally not considered as a type of lexical ambiguity. One argument supporting this claim presented in Zwicky and Sadock (1975) comes from the interaction of lexical ambiguity with VP ellipsis: if we say *Ann went to the bank and Bill did too*, then either Ann and Bill both went to a river, or they both went to a financial institution. The idea is that the meaning of the elided VP is determined after the ambiguity of lexical items such as *bank* has been resolved. Even words with semantically related but distinct senses count as ambiguous by this test: it is odd to say *Bill waved, and the flag did too*, because people wave a greeting in a sense that is distinct from a flag waving in the wind. But there is no difficulty inserting a vague predicate into a VP ellipsis antecedent even if the subjects correspond to different comparison classes. Thus it is fine to say *Bill is tall, and his six-year-old daughter is too*, even though the standard for tallness is quite different for adults versus kindergarten-age children.

Logical Behavior

Constructions involving vague predicates and especially scalar adjectives obey a number of logical rules that constrain what an adequate theory must explain. For instance, any theory should guarantee that if Bill is tall, then it certainly isn't the case that Bill is not tall. Furthermore, if the theory in question recognizes the existence of borderline cases, it must guarantee that Bill cannot simultaneously be tall and also borderline tall.

Particularly important from the point of view of theories of vagueness is the claim that vague predicates obey the law of the excluded middle, which says that a sentence like *Bill is tall or Bill is not tall* is valid (always true). Even if Bill is a borderline case, and we therefore do not know whether Bill is tall or not tall, many people judge that we nevertheless know that it must be the case that Bill is either tall or not tall.

Vagueness as Ignorance

We have seen that when asked to apply a vague predicate to a borderline case, people experience uncertainty. Williamson diagnosed this condition as ignorance: there is a fact of the matter, we just don't know which judgment is the fact. If so, then the statement *Bill is tall* is either true or false, even if sometimes we don't know which. One way of interpreting this situation is that we have only partial understanding of the meaning of a vague predicate like *tall*, and that our knowledge of its meaning remains incomplete with respect to borderline cases. This approach has the virtue of keeping intact the theorems of classical logic, including the law of the excluded middle.

Fuzzy Logic (Multivalued Logic)

A different, perennially popular strategy holds that truth itself a scalar concept: sentences are true to some degree. If tautologies are true to degree 1, and contradictions are true to degree 0, then contingent propositions may be true to any degree corresponding to a real number between 0 and 1. For instance, the claim that Bill is tall might be true to degree .76. Such theories often do not guarantee the law of the excluded middle.

Supervaluation

Van Fraassen (1966) originally proposed truth value gaps to handle presupposition failure: sentences (such as *The King of France is bald* (*see* **Presupposition**) whose presuppositions are not satisfied simply fail to have a truth value, in which case there is a truth value gap. Kamp (1975), Fine (1975), and others applied the technique of truth value gaps to vagueness. Fine in particular proposed to account for the logical behavior of vague predicates by making a distinction between truth and 'supertruth' by using valuations and supervaluations. A valuation associates each predicate with a partial function that maps the set of individuals onto a positive extension, a negative extension, or neither (this last corresponds to borderline cases). Then a valuation maps a sentence like *Bill is tall* onto true just in case Bill is in the positive extension of *tall*; it maps the sentence onto false just in case Bill is in the negative extension of *tall*; and otherwise the sentence fails to have a truth value.

The excluded-middle sentence *Bill is tall or Bill is not tall* fails to have a truth value for any valuation for which Bill is tall fails to have a truth value. But sentences can be supertrue: if every way of making a valuation more precise by dividing up the borderline cases between the positive extensions and the negative extensions results in a fully precise valuation in which the sentence comes out true, then that sentence is supertrue. For instance, no matter how we divide up the set of individuals between tall and not tall, in a fully precise valuation Bill will have to either be tall or not tall. Either way, the disjunction *Bill is tall or Bill isn't tall* will be true, so the sentence is supertrue. Though supervaluation improves on (most implementations of) multivalued logic with respect to explaining the logical behavior of vague predicates, it has two main vulnerabilities: the Sorities Paradox, and higher-order vagueness.

In a supervaluation theory, it will normally be supertrue that one grain of sand is not a heap, and supertrue that a collection of 50 million grains is a heap. The explanation for why the inductive premise seems so appealing is that for any valuation that fails to be fully precise, i.e., that classifies even one element in the sorities series as a borderline case, the inductive premise comes out true. The reason is that there is no position in the sorities series where one element is in the negative extension of a predicate and the next element is in the positive extension, because there will always be a buffer of borderline cases intervening.

However, in every fully precise valuation, there will be no borderline cases (by construction). Therefore, for every precise valuation, there will always be some number n such that n grains of sand is not a heap, but $n+1$ grains of sand is a heap. This means that the following sentence is supertrue: *There is a number n of grains of sand such that n grains of sand is not a heap, but n + 1 grains of sand is a heap*. This intuitively seems to contradict the inductive premise of the Sorities Paradox, which is one reason why some people remain unsatisfied with supervaluationism.

Higher-Order Vagueness

Fine's original supervaluation theory recognizes three crisp possibilities: a vague predicate clearly applies, it clearly fails to apply, or it clearly neither applies nor fails to apply. But just as there can be uncertainty about precisely where the border between tall and not tall falls, there can be second-order uncertainty about the boundary between clearly tall and borderline tall: is Bill clearly clearly tall, or only sort of clearly tall?

Fine (1975) and Williamson (1994, 1999) consider elaborating supervaluation theories to handle a *definitely* operator. Williamson adds a modal notion of accessibility over the class of precise valuations, so that *Bill is definitely tall* comes out as true at a world

just in case *Bill is tall* is true in that world under every precise valuation accessible from that world. As long as the accessibility relation *R* is not both transitive and symmetric, *definitely definitely p* can receive a value different from *definitely p*, and we have higher orders of vagueness as desired. The problem then becomes finding and justifying a suitable choice for the accessibility relation *R*.

Hallmarks of Vagueness

Much of language is vague, including expressions such as 'heap,' 'bald,' 'red,' 'child,' and 'hungry.' Although the exact criteria of vagueness are controversial, we can say that, at least in general, vague predicates have borderline cases and seem to lack sharp boundaries and well-defined extensions. A dieting man, Don, may at times be a borderline case of 'thin' – it is unclear whether or not he is thin. And the apparent lack of sharp boundaries to the predicate is exhibited in the fact that there does not appear to be a sudden instant during his successful diet at which Don becomes thin. Though we frequently call assertions vague if they don't supply us with enough information (e.g., 'I'll visit next week'), this is a different sense of 'vague' from that at issue here.

Vague predicates give rise to sorites paradoxes, of which the most famous is the paradox of the heap. If you have a heap of sand, and you remove a single grain, then the result will still be a heap. But then, suppose we take a heap of sand and remove grains one by one; repeated applications of that principle imply absurdly that the solitary last grain is a heap. The vagueness of other predicates accounts for the plausibility of comparable principles that can figure in sorites paradoxes, such as 'if someone is a child at time t, then she/he is a child 10 minutes later' or 'if someone of height h is tall, then so is someone one-hundredth of an inch shorter.'

Typical vague predicates also exhibit what is known as 'higher-order vagueness.' Not only does 'tall' have borderline cases at heights between the definitely tall and the definitely not-tall, but the set of such borderline cases does not seem to have sharp boundaries either. Just as it is not plausible to think there is a precise instant at which Don becomes thin, there seems

just in case *Bill is tall* is true in that world under every precise valuation accessible from that world. As long as the accessibility relation *R* is not both transitive and symmetric, *definitely definitely p* can receive a value different from *definitely p*, and we have higher orders of vagueness as desired. The problem then becomes finding and justifying a suitable choice for the accessibility relation *R*.

Hallmarks of Vagueness

Much of language is vague, including expressions such as 'heap,' 'bald,' 'red,' 'child,' and 'hungry.' Although the exact criteria of vagueness are controversial, we can say that, at least in general, vague predicates have borderline cases and seem to lack sharp boundaries and well-defined extensions. A dieting man, Don, may at times be a borderline case of 'thin' – it is unclear whether or not he is thin. And the apparent lack of sharp boundaries to the predicate is exhibited in the fact that there does not appear to be a sudden instant during his successful diet at which Don becomes thin. Though we frequently call assertions vague if they don't supply us with enough information (e.g., 'I'll visit next week'), this is a different sense of 'vague' from that at issue here.

Vague predicates give rise to sorites paradoxes, of which the most famous is the paradox of the heap. If you have a heap of sand, and you remove a single grain, then the result will still be a heap. But then, suppose we take a heap of sand and remove grains one by one; repeated applications of that principle imply absurdly that the solitary last grain is a heap. The vagueness of other predicates accounts for the plausibility of comparable principles that can figure in sorites paradoxes, such as 'if someone is a child at time t, then she/he is a child 10 minutes later' or 'if someone of height h is tall, then so is someone one-hundredth of an inch shorter.'

Typical vague predicates also exhibit what is known as 'higher-order vagueness.' Not only does 'tall' have borderline cases at heights between the definitely tall and the definitely not-tall, but the set of such borderline cases does not seem to have sharp boundaries either. Just as it is not plausible to think there is a precise instant at which Don becomes thin, there seems

to be no precise instant at which Don becomes borderline thin, or one at which he ceases to be borderline thin and becomes definitely thin. Perhaps, then, the borderline cases of 'thin' themselves have borderline cases – borderline borderline cases of 'thin.' And, moreover, those borderline borderline cases do not seem to be sharply bounded either, suggesting a hierarchy of borderline cases corresponding to the apparent lack of sharp boundaries at all levels.

Finally, note that other elements of language besides predicates are also vague: consider, for example, 'hurries,' 'quickly,' 'many,' 'very' and 'the nicest man.' Analogues of the central hallmarks of vagueness could be described in relation to these kinds of expressions.

Three Philosophical Debates About Vagueness

First, is vagueness eliminable? Many have thought not. Vague predicates seem to be an unavoidable presence in our language. As Russell (1923) argues, the application of, say, 'red' is based on unaided sense perception, and so it surely cannot be applicable to only one of an indiscriminable pair. But this thought is enough to generate a sorites paradox by considering something that changes from red to yellow through a series of changes too small for us to detect. Similarly, it can be important to have a word, like 'tall,' to pick out a vague range of a measurable quantity, like height. The applicability of other useful vague predicates can depend on several dimensions of variation – whether someone counts as 'big' can depend on both their height and their weight – or it can depend on a range of dimensions that is itself not well-defined – such as 'nice' applied to people.

Second, is there ontological vagueness? It is controversial whether it is only language and thought that can properly be called vague, or whether there can be vague objects or other vague entities. Russell thought that only representations could be vague, and Evans (1978) has argued that the idea of vague objects is not coherent, but other philosophers have attempted to make sense of the idea. This issue of metaphysical vagueness is often tackled independently of the attempt to give a theory of linguistic vagueness, with which we are concerned here.

Third, does vagueness have implications for logic? Many have thought that vagueness poses a challenge to classical logic. If Don is a borderline case of thinness, it is tempting to maintain that 'Don is thin' is neither true nor false, which is incompatible with the principle of bivalence. And the apparent lack of sharp boundaries to vague predicates is in tension with the well-defined extensions required for classical logic.

Philosophical Theories of Vagueness

A theory of vagueness faces the task of solving the sorites paradox and determining the logic and semantics of vague language.

One approach is to reject classical logic, acknowledging that borderline case predications are neither true nor false, and specifying that they have some intermediate truth-value. For example, we could adopt a three-valued logic and explain the apparent lack of sharp boundaries between the Fs and the non-Fs in terms of the range of cases between these two poles (see Tye, 1994). Or we could recognize a full range of intermediate truth-values corresponding to degrees of truth: in the region of transition from not-thin to thin, Don may count as thin to different degrees, gradually increasing from the minimum, 0, to the maximum, 1. This kind of degree theory calls for an infinite-valued logic (see Machina, 1976; for a non-standard degree theory, see Edgington, 1997).

One common objection to this kind of approach is that it merely replaces classical logic's sharp boundary between truth and falsity with other sharp boundaries between adjacent members of the new set of truth-values. So, for example, according to a three-valued logic, there will be a first instant at which Don ceases to be falsely called thin becomes borderline thin, and with a degree theory, there will similarly be a first instant at which he is thin to some degree greater than 0. Intuitively, there are no such sharp boundaries either. One way of putting the worry is that these views of vagueness cannot accommodate higher-order vagueness. Some theorists, however, (e.g., Tye) have attempted to defend a many-valued theory that is not committed to sharp transitions by appealing to the vagueness of the metalanguage in which the theory is formulated.

An alternative approach to vagueness involves accepting sharp boundaries at the first level and embracing classical logic. This epistemic view maintains that borderline case predications are either true or false – we just do not know which (see Williamson, 1994). Similarly, there is a particular instant at which Don becomes thin – we just do not know when it is. This solves the sorites paradox by denying its main premise, that is, the principle that taking a grain away from a heap will leave you with a heap. Classical logic is preserved in its entirety. The apparent lack of sharp boundaries is merely apparent, and vagueness is a matter of ignorance. Williamson (1994) has defended such a theory and provided a detailed explanation of why we are ignorant by appealing to the idea of a margin for error. If I know that someone of height h is tall, then someone of height h − e is tall, where e is less than the margin required for my belief to be

reliable. It follows that I can't know that someone slightly above the boundary is tall nor, by a parallel principle, can I know that someone slightly below it is not tall; so I can't know that the boundary falls between these two close points.

The supervaluationist theory of vagueness takes a different approach to the semantics of vague language while preserving the theorems and inferences of classical logic (see Fine, 1975; Keefe, 2000). According to this theory, 'Don is thin' is true (false) if and only if it is true (false) on all ways of making it precise, i.e., with all reasonable ways of drawing the boundary to 'thin.' If Don is borderline thin, that sentence is true on some of those ways and false on others, so it is neither true nor false. Before his diet, however, Don was definitely not thin, and it counted as false that he is thin according to supervaluationism, because any boundary that ruled him as thin at that time is not an acceptable way to make 'thin' precise. To see how the law of excluded middle still holds, despite the failure of bivalence, consider the instance 'either Don is thin or he isn't' in the case where he is borderline thin. On every way of making 'thin' precise, that disjunction comes out true, even though on some of those ways it is the first disjunct that is true, and on others it is the second disjunct. The main premise of the sorites paradox comes out false, on the other hand: on every way of drawing the boundary to 'heap,' there is some grain the removal of which turns a heap into a non-heap. But 'heap' is nonetheless not sharply bounded, because there is no particular grain whose removal marks the boundary to 'heap'; different grains mark the boundary for different ways of making 'heap' precise.

Other solutions to the sorites paradox have been proposed in addition to those embedded in the influential theories just sketched. Contextualist accounts appeal to changes in context between the assessments of different predications along a sorites series (see, e.g., Graff, 2000). Now, vague terms are typically context-dependent; whether someone counts as thin or something counts as a heap can depend on the context in which it is considered. But vagueness does not straightforwardly reduce to context-dependence, because if we fix the context, a vague term will still have borderline cases and be susceptible to a sorites paradox. Nonetheless, the contextualist approach attempts to close the gap between these phenomena with a complex and subtle treatment of context-change.

The nihilist response to the sorites paradox is one of the few that does not involve denying its main premise (see Unger, 1979). The meaning of 'heap' dictates that a heap will always survive the removal of a single grain, but the paradoxical argument does not take hold because there are no heaps. Run the case by adding grains one at a time to a single grain (adding a single grain to something that isn't a heap doesn't create a heap) and you have a sound argument with a true conclusion. This nihilist position thus renders our vague predicates empty; there are no tall people, thin people, or red things either.

To summarize, vague predicates typically have borderline cases, apparently lack sharp boundaries, and are susceptible to sorites paradoxes. For example 'is a ripe fruit' has borderline cases – a banana that is not definitely ripe and not definitely not ripe – and there is not typically a sharp point at which a fruit becomes ripe. And we can construct a sorites paradox with the notion using a premise such as 'if a fruit is not ripe at some instant, then it is not ripe one second later.' Vagueness, recall, is not merely an eliminable defect of our language; no precise replacement for 'ripe' would be usable in practice. And it poses a challenge to principles of classical logic, increasing the urgency of providing a theory of vagueness. Theories adopting a multi-valued logic will assign some intermediate truth-value between truth and falsity to the statement that our borderline-ripe banana is ripe. An epistemicist theory will maintain that such a statement is either true or false, but we just don't know which. And the supervaluationist will claim that it is neither true nor false, because it is true on some ways of making 'ripe' precise and false on others. Each of these views solves the sorites paradox by denying that the main premise is completely true, though no matter what they do to explain this, it is hard to dismiss the intuitiveness of a premise like 'if a fruit is not ripe at some instant, then it is not ripe one second later.'

Valency Grammar

D J Allerton, University of Basel, Basel, Switzerland

The Basic Idea of Valency

Valency (also known as valence, especially in the United States) is the name given in various syntactic theories (such as valency grammar, dependency grammar, word grammar, and some kinds of functional grammar) to a particular kind of dependency property exhibited by many lexical items. This kind of lexicosyntactic property involves the relationship between, on the one hand, the different subclasses of a word-class (such as verb) and, on the other, the different structural environments required by those subclasses, these environments varying both in the number and in the types of element. Valency is thus to be seen as the capacity a verb (or noun, etc.) has for combining with particular patterns of other sentence constituents, in a similar way to that in which the valency of a chemical element is its capacity for combining with a fixed number of atoms of another element (for example, one in the case of monovalent hydrogen or sodium, two in the case of bivalent oxygen or calcium, etc.). Such information is vital for language learners but was never adequately presented in traditional grammars and dictionaries.

The concept of valency is most easily illustrated with reference to verbs. Most languages have a category that roughly corresponds to or embraces the English category of verbs. Examples from English will be given here, although, where appropriate, examples from French, German and other languages will be considered.

All English verbs share syntactic and inflectional features of a very basic kind (such as their range of tensed and untensed forms, and their modification with time adverbials), but they differ radically in their requirements for accompanying noun phrases and/or prepositional phrases (with functions such as subject, object, prepositional object, etc.) that they require and/or permit.

The English verbs *stumble, jolt,* and *thrust* typically occur in distinctive environments, as in sentences like *Alfred stumbled, Alfred jolted the door,* and *Alfred thrust the key into the lock*. Putting one of these verbs into the distinctive syntactic context of one of the others gives an ungrammatical sequence like **Alfred stumbled the door* or **Alfred jolted the key into the lock*. Such restrictions mean that verbs need to be subclassified according to their syntactic potential, a fact recognized by traditional grammar in the (inadequate) division into transitive and intransitive verbs, and in modern linguistics by concepts like 'subcategorization properties,' 'syntactic frame,' or 'argument structure.' The special contribution of valency grammarians to the study of this type of subselection has been a thorough investigation of just how much is determined by the individual verb (or noun, etc.), and of how different potentials of the same verb (e.g., *Alfred pushed/ – pushed the key/ – pushed the key into the lock*) are related.

Different Conceptions of Valency

The invention of the notion of 'valency' (French *valence,* German *Valenz,* Dutch *valentie*) is often credited to Lucien Tesnière, whose *Esquisse d'une syntaxe structurale* appeared in 1953, but whose main work, *Élements de syntaxe structurale* was only published posthumously in 1959. The notion had, however, been clearly expounded by A. W. de Groot in his Dutch work, *Structurele svntaxis* (1949), and is even hinted at by Karl Bühler in an oft-quoted remark from his *Sprachtheorie* (1934), to the effect that "…words of a particular word-class open up around them one or several 'empty places', which

Valency Grammar

The Basic Idea of Valency

Valency (also known as valence, especially in the United States) is the name given in various syntactic theories (such as valency grammar, dependency grammar, word grammar, and some kinds of functional grammar) to a particular kind of dependency property exhibited by many lexical items. This kind of lexicosyntactic property involves the relationship between, on the one hand, the different subclasses of a word-class (such as verb) and, on the other, the different structural environments required by those subclasses, these environments varying both in the number and in the types of element. Valency is thus to be seen as the capacity a verb (or noun, etc.) has for combining with particular patterns of other sentence constituents, in a similar way to that in which the valency of a chemical element is its capacity for combining with a fixed number of atoms of another element (for example, one in the case of monovalent hydrogen or sodium, two in the case of bivalent oxygen or calcium, etc.). Such information is vital for language learners but was never adequately presented in traditional grammars and dictionaries.

The concept of valency is most easily illustrated with reference to verbs. Most languages have a category that roughly corresponds to or embraces the English category of verbs. Examples from English will be given here, although, where appropriate, examples from French, German and other languages will be considered.

All English verbs share syntactic and inflectional features of a very basic kind (such as their range of tensed and untensed forms, and their modification with time adverbials), but they differ radically in their requirements for accompanying noun phrases and/or prepositional phrases (with functions such as subject, object, prepositional object, etc.) that they require and/or permit.

The English verbs *stumble, jolt,* and *thrust* typically occur in distinctive environments, as in sentences like *Alfred stumbled, Alfred jolted the door,* and *Alfred thrust the key into the lock*. Putting one of these verbs into the distinctive syntactic context of one of the others gives an ungrammatical sequence like **Alfred stumbled the door* or **Alfred jolted the key into the lock*. Such restrictions mean that verbs need to be subclassified according to their syntactic potential, a fact recognized by traditional grammar in the (inadequate) division into transitive and intransitive verbs, and in modern linguistics by concepts like 'subcategorization properties,' 'syntactic frame,' or 'argument structure.' The special contribution of valency grammarians to the study of this type of subselection has been a thorough investigation of just how much is determined by the individual verb (or noun, etc.), and of how different potentials of the same verb (e.g., *Alfred pushed/ – pushed the key/ – pushed the key into the lock*) are related.

Different Conceptions of Valency

The invention of the notion of 'valency' (French *valence,* German *Valenz,* Dutch *valentie*) is often credited to Lucien Tesnière, whose *Esquisse d'une syntaxe structurale* appeared in 1953, but whose main work, *Élements de syntaxe structurale* was only published posthumously in 1959. The notion had, however, been clearly expounded by A. W. de Groot in his Dutch work, *Structurele svntaxis* (1949), and is even hinted at by Karl Bühler in an oft-quoted remark from his *Sprachtheorie* (1934), to the effect that "…words of a particular word-class open up around them one or several 'empty places', which

have to be filled by words of certain other word-classes" (1934: 173).

It is nevertheless preeminently Tesnière's notion of valency that has been studied and developed in continental Europe, especially Germany, since the 1960s. On the one hand, valency has been integrated with 'dependency theory' by such scholars as J. Ballweg, U. Engel, B. Engelen, H-J. Heringer, J. Kunze, H. Schumacher, and H. Vater; on the other, it has been applied to the detailed description of, most notably, German by G. Helbig and the Leipzig school, but also of English (D. J. Allerton, R. Emons, and T. Herbst), and French (W. Busse and J.-P. Duhost). (For a historical survey up to the mid-1970s, see Korhonen, 1977.) The following review of the problems of valency theory will take Tesnière's proposals as a starting point.

Tesnière's Approach

Valency can be incorporated into a functional type of constituency grammar (involving relationships between the subcategorization of neighboring constituents), but for Tesnière, it was one aspect of dependency grammar. His semantically based syntax was concerned with establishing the hierarchy of word 'connexions' within a sentence, which make up the what he termed the 'structural order' of words (as opposed to their linear order). The structural order of each sentence is given in terms of a 'stemma,' a two-dimensional display, in which the top-to-bottom dimension represents a series of relationships between 'governors' (or 'heads,' French *régissants*) above and 'dependents' (French *subordonnés*) below. Typically in a 'governor-dependent relationship,' the governor may occur without the dependent but not vice versa, and the governor provides the central semantic element, whereas the dependent only represents a modification of this element.

A consideration of the partial structural stemma of (A) in **Figure 1** enables us to appreciate a number of points about Tesnière's approach: a first point is that the governor-dependent relationship can operate at different levels (with *old* acting as dependent of *the grammarian*, but as governor of *very*); a second point is that one governor (like *the grammarian*) can have more than one dependent (*old* and *French* in this case), but not vice versa; finally, a 'semantically empty' word like *the* can combine with a 'full' word like *grammarian* to form a single 'nucleus' (marked with a 'circle'), that is, a single point on the stemma. Each governor is said to act as a 'node' (French *noeud*) for all of its direct and indirect dependents, so that *the grammarian* acts as a node for the whole of the stemma of (A) in **Figure 1**.

In a typical sentence, like that of (B) in **Figure 1**, Tesnière saw the main verb as the 'central node' (*noeud des noeuds*). The verb achieves this central role through its high position in the hierarchy of connexions but also through its ability to determine the number and variety of its dependents. But the question of how many dependents a verb has is no simple matter. In fact, Tesnière distinguished two types of dependent for verbs, to which he gives the labels 'actants' and 'circonstants.' From a semantic point of view, the 'actants' represent the participants, while the 'circonstants' represent the setting and incidental details of the process or state expressed by the verb, the whole sentence portraying a minidrama. In the example of (B) in **Figure 1**, where *offered* represents the process, *Alfred, (that) Bible,* and *to Charles* would be 'actants,' while *repeatedly, in Strasbourg,* and *on Tuesday* would be 'circonstants.'

An Essential Distinction: 'Actants' versus 'Circonstants'

Everything so far noted about Tesnière's views has been a matter of general dependency theory, but the distinction between 'actants' and 'circonstants' is distinctively the preserve of valency theory. 'Actants' belong to the valency of individual verb types, whereas 'circonstants' are in principle potential dependents in any sentence, regardless of the verb. Thus the constellation of 'actants' represented in (B) in **Figure 1** is characteristic of one subclass of English verbs that includes not only *offer* but also *give, lend, refuse, sell, send,* and a couple of dozen others.

In (B), *Alfred, that Bible,* and *to Charles* would be termed by Tesnière first, second, and third 'actant' respectively, and these terms correspond to what in English grammar are normally called subject, (direct) object, and indirect object respectively. These are the only elements that Tesnière recognized as 'actants' in active sentences. This choice is unfortunate, because many prepositional phrases are equally essential to the verb, such as the prepositional object *on Barbara* in *Alice relied on Barbara*, and even purely adverbial phrases are required by certain verbs, such as *live (at home,* etc.), *last (for two hours,* etc.), or *thrust,* which, as noted earlier, needs both an object and a specification of place.

The subclass of verbs that includes *offer, give,* etc. is described as 'trivalent,' because its members require three 'actants'; the same could be said of the subclass of *thrust, put,* etc., although Tesnière did not recognize this. Ordinary transitive verbs like *jolt* or *like, kill,* etc., which merely require a subject and a direct object, are termed 'bivalent' (or 'divalent'); and the same applies to copular verbs like *be, seem*, or

Figure 1 Stemmas and kinds of dependent.

become that take an adjectival or nominal predicative (complement) such as *beautiful* or *a beauty*. Finally, ordinary intransitive verbs like *stumble* or *deteriorate, sneeze*, etc. are described as 'monovalent'. (For 'zero-valent' (or, to use Tesnière's term, 'avalent') verbs, see the section 'Levels of Analysis').

By contrast with 'actants,' the adverbials of (b) are not relevant to valency classification. Thus *repeatedly,* an adverbial of frequency, *in Strasbourg,* a positional adverbial of place, and *on Tuesday,* a punctual adverbial of time, could all just as well have occurred with the different verb subclasses represented by *stumble, jolt,* and *thrust,* in fact, with any verb at all. Tesnière (1966: 125) mistakenly insisted that such adverbials are unlimited in number (by contrast with the fixed number of 'actants'), but the essential point is their universality, their freedom to occur in any sentence.

Through the history of valency theory and grammatical theories such as transformational grammar (cf. Baker, 1989: 266–267) and systemic grammar (cf. Halliday on 'participant roles and circumstantial roles'), various technical terms have been used to refer to the distinction between these two kinds of dependent of a governor (or head). These are listed in (C) in Figure 1. For clarity's sake, the terms 'verb elaborator' and 'free modifier' will henceforth be used for the post-Tesnièrian equivalents of 'actant' and 'circonstant.' (The term 'complement' has frequently been used in the sense of elaborator, but it has the disadvantage that for traditional grammarians and many modern ones, it has a quite different meaning and may exclude the subject, which the terms elaborator and 'actant' never do. The more modern term 'argument' is unfortunate for a different reason: to the uninitiated, it suggests a whole sentence or clause rather than the sentence constituent that it is.)

Whatever the terminology, there is a consensus about the need for a distinction between elaborators

and free modifiers, but there are certain problems associated with it. Clearly Tesnière oversimplified matters by insisting that, in principle, elaborators (i.e., 'actants') were essentially nominal in form and semantically necessary to the verb, while free modifiers (i.e., 'circonstants') were adverbial in form (comprising adverbs and prepositional phrases) and semantically not required by the verb. German valency theorists, such as Helbig, Heringer, and Herbst, have proposed tests for distinguishing the two kinds of dependent. Helbig, for instance, suggested that in sentences like the following:

(1) Alice ate the sandwich in the train.

(2) Alice put the sandwich in the fridge.

the status of the adverbial phrases differs partly because *in the train* is omissible while *in the fridge* is not, but also because the first phrase, though not the second, has regularly corresponding sentences of the form:

(3) Alice was in the train when she ate the sandwich.

(4) What Alice did in the train was $\left\{\begin{array}{l}\text{(to) eat}\\ \text{she ate}\end{array}\right\}$ the sandwich.

These correspondences to related sentences seem to indicate that *in the train* in (1) is a free modifier or 'adjunct,' whereas *in the fridge* in (2), though an adverbial, is a verb elaborator, just like the earlier examples of obligatory adverbials with the verbs *live, last,* and *thrust*.

All obligatory elements are therefore verb elaborators, but this does not mean that all optional elements are free modifiers. Even Tesnière only suggested that elaborators ('actants') are "often indispensable to complete the sense of the verb" (1966: 128). Helbig therefore proposed a three-way division into obligatory elaborators, optional elaborators, and free modifiers (*obligatorische Ergänzungen*, *fakultative Ergänzungen*, *freie Angaben*). The following examples suggest the need for an even more subtle analysis:

(5) Alfred was praising the play.

(6) Alfred was watching [the play].

(7) Alfred was reading (the play).

(8) Alfred was idling.

The first three have *the play* as the object of the verb and therefore as a potential part of its valency, but it is only in the first sentence that the object is obligatory. In both the second and the third sentences, *the play* may be omitted, but under different conditions: whereas in (6) the objectless version of the sentence always requires the listener to identify the thing watched from what is evident in the context, in (7) the objectless sentence leaves the thing read totally open as a matter of no immediate interest (cf. Allerton, 1982: 68–70). Thus while the optional object is clearly part of the valency of *watch* in all its uses, the verb *read* appears to have two different valencies, only one of them involving an object. In (8), finally, no object is possible with the unequivocally intransitive verb *idle;* an object can therefore be no part of its valency. This truism suggests a useful general test: if an element, such as an object noun phrase, can only be added to certain verbs and not to others, then it participates in verb valency, in contrast to, say, a time adverbial like *yesterday* or *today,* which can be freely added to any sentence (given an appropriate tense form). The test of insertion, rather than that of omission, is therefore most useful for distinguishing elaborators from free modifiers.

The Diversity of Elaborators

Further tests are required for deciding what kinds of elaborator need to be distinguished. A substitution test, for instance, is useful in assessing combinations of verb and prepositional phrase. All the prepositional phrases in the following sentences are omissible elaborators, and yet they do not all have the same status:

(9) Alice listened to the big waves.

(10) Alice concentrated on the big waves.

(11) Alice swam to the big waves.

(12) Alice floated on the big waves.

A consideration of the first two sentences, (9) and (10), shows not only that the preposition is selected by the verb, but even that no other preposition is possible without a change in the nature of the combination; the prepositional phrase is therefore some kind of prepositional object (a category not allowed for by Tesnière but standard in German valency grammar). The prepositional phrases in (11) and (12), however, are not prepositional objects, as various tests show: the preposition can be replaced with a range of other prepositions to give a series of regular semantic contrasts (*to* → *into, towards, under,* etc.; *on* → *over, near, behind,* etc.); unlike the prepositional phrases of (9) and (10), those of (11) and (12) demonstrate their place-adverbial nature through their capacity for being preceded by particles like *right* or *back*; finally, whereas the phrases of (9) and (10) show their partly nominal nature through their elicitation with a *What* + preposition question, those of (11) and (12) are typically elicited with the

Where (... to) question typical of place adverbials of location and destination respectively.

These and similar criteria have been referred to by valency grammarians as establishing the various possible elaborators of verbs. It has become clear that these elaborators include not only noun phrases but also prepositional phrases and adverbs. They also include adjective phrases, as in the first two ((13a) and (13b)) of the following sentences:

(13a) Alfred seemed rather stupid.
(13b) Alfred remained fit.

(14a) Alfred seemed a fool.
(14b) Alfred remained an athlete.

(15) Alfred insulted an athlete.

The first two pairs of these sentences, i.e., (13a)/(13b) and (14a)/(14b), illustrate the pattern of a verb with what is in traditional grammar called a complement but in most modern works is referred to as a 'predicative' (following Jespersen). Most typically, this pattern contains an adjective phrase, as in (13), but where it is a noun phrase, as in (14), the noun phrase may generally be replaced with an adjective phrase (hence the alternative label 'predicate nominal/adjectival'). One way in which predicatives differ from objects is in their nonacceptance of 'clefting,' with the result that, comparing (14) with (15), we find that **It was an athlete that he remained* is not a possible sentence, while *It was an athlete that he insulted* is perfectly natural.

Noun phrases and adjective phrases are the two universally described kinds of predicative, but there is a third kind, in the form of a prepositional phrase, as in (16):

(16a) Alfred seemed in a funny mood.
(16b) Alfred remained in good health.

The prepositional phrases *in a funny mood* and *in good health* in these sentences have a similar function to the adjectival phrases *rather stupid* and *fit* in (13a)/(13b); it seems only reasonable then to recognize them as prepositional predicatives, alongside nominal and adjectival ones. In such prepositional phrases, the preposition has a weak semantic contribution to make and is selected by the noun (cf. *under a misapprehension, on top form*).

Returning to noun phrase predicatives, we see that they can be formally identical to noun phrase objects. Clearly predicatives and objects are noun phrases with rather different functions, and it can be argued that function is a vital ingredient in the specification of elaborators, particularly in a noncase language like English. In addition to the 'clefting' test just mentioned, 'passivization' of a sentence, in particular, the moving of an active object to subject position in the corresponding passive clause (e.g., changing (15) above to *An athlete was insulted by Alfred*), can play a part in evaluating such functions. It is worth noting, however, that not all the noun phrases traditionally classed as objects pass this test, and if this is taken to be the hallmark of objecthood, some will need to be thought of as pseudo-objects or 'objoids.' In a language like German, on the other hand, it might be sufficient to define elaborators with such labels as accusative object, dative object, prepositional object, etc. and regard the predicative as a nominative kind of object, since passivization is not limited to sentences with any one kind of object (though, admittedly, only the accusative object can become the passive subject).

One final type of elaborator needs to considered. As a variation of (11), we might cite (17), which differs only in having its adverbial (elaborator) in the shape of a single word adverb instead of a prepositional phrase. It needs to be contrasted with (18), in which the single word adverb has a rather different function:

(17) Alice swam out.

(18) Alice turned out.

Whereas the normal adverbial elaborator *out* in (17) participates in normal semantic contrasts like *swam out* versus *swam in* versus *swam across*, and can be compared with the fuller form *swam out of the lagoon*, the *out* of (18) has a quite different status. The contrast between *turn out* ('appear on duty') and *turn in* ('go to bed') is not the normal one between *in* and *out*, and the combination *turn across* is virtually nonoccurrent. Combinations like *turn out* (or *turn in*) are not normal sequences of verb and adverbial elaborator but tight collocations of the type usually referred to as 'phrasal verbs,' and in these collocations, the adverb has a strong limiting effect on the meaning of the verb, so that *turn*, for instance, has to be understood in a special new sense. Such adverbs (and it is only a question of single-word adverbs) can be described as limiter adverbs.

One view of the total range of English verb elaborators other than the subject is given for bivalent verbs in Figure 2. After each elaborator, a suggested abbreviatory symbol is given in parenthesis.

The Special Status of Subjects

The range of English verb elaborators displayed in Figure 2 expressly excludes the subject. But, as noted above, valency grammarians differ from other grammarians in seeing the subject not as standing apart from the predicate or verb phrase but rather as

Figure 2 Nonclause elaborators of English bivalent verbs, excluding the subject (**S**).

standing alongside the object as an elaborator. As Tesnière put it (1966: 109), "*... du point de vue structural... le sujet est un complément comme les autres*"; but this statement is something of an oversimplification.

The subject has a special place as regards inflectional morphology. In languages that have grammatical case, there is frequently a case such as the nominative that is selected for active subjects regardless of the lexical verb used, whereas verbs may govern objects in at least two different cases (as in German or Russian). As for the verb's own inflections, these commonly agree with the number, person, etc. of the subject but not the object, whereas the reverse never obtains. Languages with an ergative/absolutive case system, like Basque, are slightly different in these two respects.

In terms of syntactic form, subjects have greater positional prominence in the sense that, in the absence of a specially marked theme, the subject occurs typically as the first noun phrase in the

sentence – a feature shared by SOV, SVO, and VSO languages, that is, well over 90 percent of the world's languages. As regards syntactic dependence for occurrence, the subject normally has a higher priority than the object, in the sense that with all verbs, or (depending on the language) the vast majority of them, a subject is obligatory, while an object is only required by a proportion of verbs (i.e., by transitive ones). It is of course true that many languages – so-called pro-drop languages like Spanish, Italian, or Japanese – allow the subject to be omitted when it is identifiable from the linguistic or situational context (e.g., Spanish *vino* 'he/she/it came'). But these languages further allow the objects of many verbs to be omitted with no requirement of contextual recoverability (just like English *read,* discussed above, cf. Spanish *leyó* 'he/she/it read (something)'); and of course purely intransitive verbs (like Spanish *venir* 'come') reject objects altogether.

Finally, the subject (but not the object) has a textual role in being the typical sentential theme, one often carried forward from previous sentences, and is often phonologically marked as such (in English, for instance, often through a separate intonation unit). On the whole, then, subjects stand apart from other verb elaborators and need to be accorded a special status *vis-à-vis* the verb; but they are elaborators nonetheless.

Levels of Analysis

The above discussion of subjects and objects partly presupposes a clear definition of these categories. But this issue is a complex one, in which much hinges on the relationship between transitive active sentences and passive sentences as well as sentences with other formats. Consider a pair of sentences like:

(19) Alice attacked Barbara.

(20) Barbara was attacked by Alice.

According to most criteria (position, agreement, obligatoriness, for instance), *Alice* is the subject of (19), whereas *Barbara* is the subject of (20) despite the virtual synonymy of the two sentences. Tesnière accepted such an analysis but noted that the subject of the passive, *Barbara,* has the same semantic role ('patient' or 'sufferer' of the verbal action) as the object of the active sentence; whereas the subject of the active sentence, *Alice,* has the same semantic role ('agent') as the passive agentive phrase, *by Alice,* which he termed 'counter-subject' (French *contre-sujet*). What Tesnière failed to note is that these semantic roles are not valid for all active and passive subjects, objects, and counter-subjects; rather, it is a matter of the semantic valency requirements of individual verbs, as exemplified by the similar correspondences observable in the following sentences:

(21) Alice liked Barbara.

(22) Barbara was liked by Alice.

(23) Alice pleased Barbara.

(24) Barbara was pleased by Alice.

Thus, while in the first two sentences, (21) and (22), with *liked,* the active object and the passive subject, *Barbara,* agree in being the causer or stimulus of the emotion described by the verb, in the last two sentences, (23) and (24), with *pleased*, it is the active subject and passive 'counter-subject' (termed 'perject' in Allerton, 1982), *(by) Alice*, that have this kind of role. There is a similar exchange of syntactic functions between the *liked* sentences and the *pleased* sentences for the other semantic role of 'mental experiencer.' So while precise semantic roles are determined by the meaning of individual verbs (cf. also *defeat* and *lose (to)*), there is, given sentences containing any particular verb, a crucial correspondence between the syntactic functions of the active and the passive format of related sentences, and therefore a need to recognize a level of analysis independent of and intermediate between superficial subjects and objects on the one hand and purely semantic roles on the other. This recognition is of the valency level of deep or underlying subjects and objects.

A further reason for recognizing this underlying valency level of description is the behavior of certain meteorological verbs, as exemplified by English *It was raining,* French *Il pleuvait,* and Spanish *Llovía*. In Spanish (and other pro-drop languages), it is impossible to have a subject with such verbs in their normal use, and the verb *llover* can be said to be zero-valent (or 'avalent,' to use Tesnière's term). In English and French, the words *it* and *il* respectively fulfill the requirements discussed above to qualify as superficial subjects; but such a subject has no clear semantic role and is not replaceable (by such a phrase as *the weather*), and it seems that it may simply be part of the required surface structure for English and French sentences without corresponding to a true valency subject. For the corresponding German form *Es regnet*, the situation appears to be slightly different, because sentences without a (nominative) subject do occur, e.g., *Mich friert* 'Me is freezing = I am freezing,' *Mir ist kalt* 'To-me is cold = I am cold,' *Mir wurde geholfen* 'To-me was helped = I was helped'). (N.B. The initial pronoun in these sentences is the theme but not the subject.) It could therefore be argued that, since this empty German *es* is not required by any

	Valency gap	*Valency subject*	*Valency object*
Sentence with:			
Zero-valent verb (e.g. *rain*)	SURFACE SUBJECT	—	—
Monovalent verb (e.g.*stumble*)	—	SURFACE SUBJECT	—
Divalent verb (e.g.. *jolt*)			
— active	—	SURFACE SUBJECT	SURFACE OBJECT
— passive	—	PERJECT*	SURFACE SUBJECT

* = Tesnière's 'contre-sujet,' often referred to simply as 'agent phrase,' although this is often semantically inappopriate.

Figure 3 Correlation of English valency and surface functions.

general rule of sentence structure but is demanded by such meteorological verbs, it is a required (though empty) elaborator.

A summary of the relationships between valency functions and surface form in English meteorological sentences, ordinary intransitive, and transitive sentences. both active and passive, is given in Figure 3.

Trivalent verbs of the indirect object type discussed (like *offer* and *give),* also appear in two virtually synonymous formats in English, as exemplified by:

(25) Alfred handed that Bible to Charles.

(26) Alfred handed Charles that Bible.

These two formats can be regarded as variant realizations of the same valency pattern, with the indirect object appearing either after the object and with a preposition (as in (25)) or before it and without a preposition (as in (26)). Each version gives rise to a different passive sentence (*That Bible was handed . . ./ Charles was handed . . .*).

Different Links between Elaborators and Semantic Roles

Rather different in its valency implications is the kind of obligatorily reflexive verb exemplified by *absent oneself* in (27), compared with the incidentally reflexive verb of (28):

(27) Alice absented herself from the meeting.

(28) Alice criticized herself at the meeting.

Since a nonreflexive object is impossible with the verb *absent,* the *herself* of (27) is an empty elaborator that cannot be said to express an independent semantic role beyond that of the subject, which in this case can be described as agent. In (28), on the other hand, *herself* has the role of patient (or affected entity), with the subject again having the role of agent. But in both cases, the reflexive pronoun fulfills the valency function of object, a (prepositionless) noun phrase immediately following the lexical verb, so that both verbs can be regarded as bivalent.

This view of the valency of reflexive verbs differs from that of Tesnière, who saw reflexive verbs as manifestations of a different kind of verbal voice, the so-called recessive (French *récessif),* which reduced the valency of a verb by one, so that bivalent verbs like *lever* 'raise,' or *ouvrir* 'open (transitive)' become monovalent when reflexive *(se lever* 'rise, stand up,' *s'ouvrir* 'open (intransitive)'). Although this view is an interesting one, it is something of an oversimplification.

In fact, reflexive verbs in French (and many other languages, including German), seem to have at least four possible different kinds of status. A first group of verbs, like *se laver* 'wash oneself' or *se critiquer* 'criticize oneself' are ordinary transitive verbs that can have a reflexive object as an alternative to a normal one, but the reflexive one has no special significance for verb valency. A second group of verbs, like *s'absenter* 'absent oneself' or *se souvenir (de)* 'remember,' do not have a nonreflexive use, and thus the reflexive pronoun is an empty elaborator, even though an essential one, rather similar to the *es* of German *Es regnet* (discussed in the section Levels of Analysis). Thirdly, there are verbs like *douter/ se douter* 'doubt/imagine, suspect' or *résoudre/se résoudre (à)* 'solve/decide,' which have both a nonreflexive and a reflexive use, but where the semantic difference is too great for them to be simply counted as the same verb; in fact, reflexivization is used almost like a device of word-formation for producing a new lexical item, one that has to count as a compulsorily reflexive verb. Finally, there are verbs like *ouvrir* and *vendre,* for which the reflexive pattern is used to convey the idea that the subject is semantically the

patient (and hence also object), and that there is no explicit agent, which is why the patient has to fill the subject position too, as in *La porte s'ouvre* 'The door opens (itself).' This reflexive use truly is a way of coping with a reduced number of semantic roles and gives rise to 'polyvalency,' that is, a verb displaying an equivalent meaning in two quite different grammatical uses.

Tesnière also recognized syntactic devices for increasing the valency of verbs, such as French causative constructions with *faire*. English causative constructions with *have, make, cause,* etc. preserve subject and object functions in the embedded infinitive clause of sentences like those of (29) and (30) below, so that *Alfred* remains the subject and *Balzac* the object of the verb *(to) read,* just as they would have been in a full sentence with the same content *(Alfred reads Balzac,* for instance):

(29) John had Alfred read Balzac.

(30) John caused Alfred to read Balzac.

In French, on the other hand, *faire* seems to combine with infinitives to form complex verbs like *faire mourir* 'have . . . die,' *faire apprendre* 'have . . . learn,' and *faire donner* 'have . . . give' to give sentences like the following (adapted from Tesnière), in which *Jean* is introduced as the causer or instigator and as subject of the whole *faire* + verb complex, displacing *Alfred* from subject position:

(31) Jean fait mourir Alfred.
(cf. Alfred meurt.)

(32) Jean fait apprendre le bulgare à Alfred.
(cf. Alfred apprend le bulgare.)

(33) Jean fait donner la Bible à Charles par Alfred.
(cf. Alfred donne la Bible à Charles.)

As Tesnière pointed out (1966: 260–262), French requires that the displaced subject should occupy the next available place down the hierarchy, starting with the object (= second actant) as in (31), going on to the indirect/ prepositional object (= tierce actant) as in (32), and going on as far as the agent phrase (= quatrième actant) as in (33).

Other languages have different ways of dealing with the valency of causative relationships. One possibility is to allow polyvalency in such a way that the same verb may be used intransitively and transitively in a causative sense without change of form, as with the many so-called ergative verbs of English, which typically refer to a change of state or position. Verbs such as *break, cook, open, boil,* and *sink* have a monovalent use as in (34) below, beside a bivalent one with a causative meaning as in (35):

(34) The glass broke.

(35) John broke the glass.

With such verbs, the subject of the intransitive pattern and the object of the transitive pattern have the same semantic role of 'patient affected,' while the transitive subject has the role of 'agent.'

An alternative way of dealing with different constellations of elaborators with semantic roles is by marking the particular valency pattern by means of derivational morphology, i.e., having a related verb derived with an affix to create a verb of different valency: the German prefix *be-,* for instance, often has the effect of converting an intransitive verb into a transitive one, as in the pairs *arbeiten/bearbeiten* 'work/work on, process' and *enden/beenden* '(come to an) end/(bring to an) end, complete'. Swahili has a range of suffixes that work in a similar way:

-w(a)	dynamic passive	e.g., *-vunjwa* 'be(come) broken'
-ík(a)/-ek(a)	stative passive	e.g., *-vunjika* 'be/ remain broken'
-an(a)	reciprocal	e.g., *-pendana* 'see each other'
-i(a)/-e(a)	applicative	e.g., *-letea* 'bring to (someone)'
-sh(a)/-z(a)/-ny(a)	causative	e.g., *-angusha* 'make fall = drop'

All of these Swahili suffixes give rise to sets of related verbs with different constellations of elaborators with semantic roles, but these constellations are of different kinds. The applicative and the dynamic passive (like the English passive) reassign elaborators: the object in the applicative corresponds to a normal preposition phrase; the subject in the dynamic passive corresponds to a normal object. The stative passive involves reassignment of the object to subject position but loss of the original subject. The reciprocal reduces bivalent subject-object structure to a simple monovalent one. The causative and the applicative increase the valency: the causative includes a new 'instigator' subject, downgrading the normal subject to object, while the applicative introduces a new 'indirect patient' as object, downgrading the normal object to a kind of secondary object.

Patterns Involving a Transcategorial Quasitransformational Relationship

Apart from the regular, transformational relationships that we find between active and passive structures or

in other cases of polyvalency, there are some more distant and less regular cases of valency pattern relationships that need to considered. These are cases in which not simply the elaborators of the verb are reconfigured in some way, but ones in which the verb itself is involved in the restructuring. Unlike active-passive and similar regular transformational relationships, these partly irregular relationships are like word-formation patterns in their partial unpredictability, so that it would be reasonable to refer to them as 'quasitransformational' patterns of correspondence.

Consider the following examples:

(36) Alfred greatly enjoyed the music.

(37) Alice really loved Mozart.

(38) Alfred derived great enjoyment from the music.

(39) Alice really was in love with Mozart.

The sentences of (36) and (37) are simple bivalent structures with subject and object as verb elaborators, whereas their quasi-synonymous kindred sentences, (38) and (39) respectively, involve a different pattern. In this more complex structure, a semantically lightweight verb is used, pushing the verb's meaning into an elaborator position, object position in the case of (38) and noun phrase within a prepositional predicative in (39). Although the valency of the simplex verbs *enjoy* and *love* is identical (i.e., they are both bivalent, with a 'mental processor' subject and a 'mental focus' object), the corresponding nouns (*enjoyment* and *love*) participate in quite different patterns and are anything but interchangeable. In Allerton (2002), sentences like those of (38) and (39) are said to involve 'stretched verb constructions,' and the relationship of their structure to that of their kindred simpler 'unstretched' structure is represented by marking the functions of their elaborators with the capital letters used already (**S, O,** etc.) and by attaching to every descriptive category an oblique stroke (or 'slash') followed by a lowercase letter indicating the corresponding element in the equivalent 'unstretched' structure. Elements that have no correlate in the simple verb structure are labeled as . . . **/ø**. Sentences (38) and (39) could be represented at a valency level as (38x) and (39x) respectively:

(38x) Alfred derived great enjoyment from the music.
S/s + V/ø + O/v + PÖ/o

(39x) Alice really was in love with Mozart.
S/s + V/ø + PD/v + PÖ/o

The collocation *derive enjoyment from* has a meaning that is not essentially different from *enjoy*, so that semantically such correspondences obtain. But grammatically, even at the deeper valency level, *derive* is a verb and *enjoyment* is a noun. Such quasi-transformational relationships between 'kindred' constructions are therefore semantic in nature but need to be recognized as involving a grammatical correspondence that is transcategorial. The existence of stretched verb constructions gives the speaker a wide choice between different verbal construction types to express broadly the same meaning, as the further examples of (40) show.

Each of the options given in (40a)–(40f) represents a different grammatical structure, with a different relationship to the underlying sentence (40), which has the action expressed by a verb. Compared with the simplex structure of (40), the eventuality type named by the verb has been 'moved' into a verb elaborator position (predicative or prepositional objoid or object) and there have been reallocations of the verb elaborators themselves. In the structure of (40b), a 'former' object has been downgraded to the position of a prepositional phrase qualifier (**PQ**) of a verb elaborator, which in this case is a nominal predicative (**ND**):

(40) The child helped the teacher.
S + V + O

(40a) The child was helpful to the teacher.
S/s + V/ø + AD/v + PÖ/o

(40b) The child was a helper of the teacher.
S/s + V/ø + ND/v < PQ/o>
(where the **ND** is agent-oriented)

(40c) The child was a help to the teacher.
S/s + V/ø + ND/v + PÖ/o
(where the **ND** is process-oriented)

(40d) The child was of help to the teacher.
S/s + V/ø + PD/v + PÖ/o

(40e) The child came to the help of the teacher.
S/s + V/ø + PÖ/v + PÖ/o

(40f) The child gave help to the teacher.
S/s + V/ø + O/v + IO/o

What all stretched verb constructions share is the way the process of helping is signaled by an adjective or noun rather than the verb. The verb in such constructions has been variously described as a light or thin verb, or as a support verb, because its semantic contribution is so weak. In English stretched verb constructions with a copular verb, the standard verb is of course *be*, but otherwise, the verb seems to have been selected from a limited list of possibilities: intransitive patterns like (40e) have *come, go, put, meet,* and *provide* or some such similar verb, while in transitive ones like (40f) the most common verb is

make, with *carry out, feel, get, give, have, provide, receive, suffer* and *take* also being frequent.

Adjective and Noun Valency

Although Tesnière confined valency to verbs, it has been naturally extended to adjectives and nouns by later valency grammarians. Predicative adjectives combine with copular verbs to form a unit that has many features in common with verbs, including similar valency requirements, for instance, *be afraid (of)* can be compared with *fear.* Admittedly the adjective (phrase) *afraid (of)* can be regarded as an elaborator of the verb *be;* and it is true that predicative adjective phrases occur with various verbs other than *be,* such as *become, remain, seem* (not to mention the trivalent *make (someone/something …)*, *keep (someone/something …)*, etc.), and thus involve a second order valency. On the other hand, the adjective's valency extends beyond what is normally termed adjective complementation, as in *afraid of the dark,* to cover the subject of its companion verb. An adjective like *afraid,* for instance, requires an animate subject with the role of experiencer. Other predicative adjectives have requirements that link subjects with other elaborators, as the following examples demonstrate:

(41) Alfred is similar to Alice.

(42) Alice and Alfred are similar (to each other).

(43) [Alice is mad about cars.] Alfred is similar.

Clearly *similar (to)* implies two entities, but these can be referred to in three different patterns: in (41), one entity is the subject and the other occurs as a (following) elaborator of the adjective; in the (42) pattern, which involves a reciprocal meaning, the subject must be plural, and the adjective's elaborator is freely omissible; in the (43) pattern, finally, the elaboration of the adjective has to be supplied from the context (just like the object of the verb *watch,* discussed in the section An Essential Distinction: 'Actants' versus 'Circonstans'). The elaboration patterns of such adjectives thus cannot be adequately described without reference to the subject.

Most English adjective elaborators are like verb elaborators in that they follow the word they elaborate. There is, however, one important difference: while the majority of verb objects have no preposition in English, virtually all adjectives do require a preposition before their complement (the one clear exception being *worth).* As in the case of prepositional verbs, the adjectives each select a particular preposition, in an often arbitrary way, for example, *keen on, eager for, dependent on, independent of, free of/from.* Sometimes the adjective's choice of preposition agrees with that of a corresponding verb, sometimes the verb has a different preposition, or no preposition at all:

(44) Alice was hopeful of success.
(cf. Alice hoped for success.)

(45) Alice was hungry for power.
(cf. Alice hungered for power.)

(46) Alice was desirous of wealth.
(cf. Alice desired wealth.)

Adjectives with more than one elaborator are relatively rare but can be found, for example, *responsible to (someone) for (something).*

In case languages, some elaborators of adjectives occur without a preposition, but instead, they occur in a particular case form required by the adjective. In German, this case is most commonly the dative, and such elaborators most commonly precede the adjective, as in (47) below; on the other hand, *anders* 'different', is complemented with the case-neutral subordinator *als,* which follows, as in (48):

(47) Alfred ist seinem Bruder sehr ähnlich.
(cf. Alfred is very similar to his brother.)

(48) Alfred ist ganz anders als sein Bruder.
(cf. Alfred is quite different to/from his brother.)

(Note that *sehr* 'very' and *ganz* 'quite' are free modifiers and thus strictly outside adjective valency; the preference for the one or the other in these cases is determined semantically rather than lexicogrammatically.)

Noun valency is comparable with adjective valency, particularly for nouns derived from adjectives, though the selection of prepositions in noun complements, too, only partly corresponds to that in related words (i.e., adjectives and verbs), as illustrated by these examples:

(49) Alice's dependence on her parents (was obvious).
(cf. Alice was dependent on her parents.
Alice depended on her parents.)

(50) Alfred's pride in the project (was obvious).
(cf. Alfred was proud of the project.
Alfred prided himself on the project.)

Noun valency therefore also needs to be specified independently. It even has special features of its own. In the first place, there are many nouns without a corresponding verb or adjective that take a complement, for example, *daughter (of…), president (of…), headquarters (of…), advantage (of…), appetite (for…).* A second point made clear by the above examples is that of the English *of,* which often counts as the equivalent of a genitive case in case languages,

is the favored preposition; thus an *of* noun complement often corresponds to the simple object of a transitive verb (without a preposition), for example, *bombardment/defence/siege of the castle* (cf. *bombard/defend/besiege the castle)*, although even here there are exceptions, such as *attack on the castle*. The most striking feature of noun valency, however, is the fact that the item corresponding to the subject of a verb, particularly of a transitive one, can appear in a language like English as a possessive determiner (i.e., in place of an article), as an alternative to its occurrence as a prepositional complement, as the following examples show.

(51) a/the defeat, a/the collapse [simple *determiner* + NOUN]

(52) Alfred's collapse, the collapse of Alfred, *the collapse by Alfred.

(53) Bernard's defeat (?by Alfred), the defeat of Bernard by Alfred,
Alfred's defeat of Bernard, *the defeat of Alfred of Bernard

Although complex interrelationships are involved in the above, and borderlines are not always clear, it can be said that *by* complements normally correspond to transitive subjects, possessives to transitive or intransitive subjects (and occasionally objects), and *of* phrases to intransitive subjects or to objects. Furthermore, two complements of the same kind are not allowed.

Embedded Clauses as Part of Valency

Many verbs, adjectives, and nouns, besides their normal valency patterns involving phrases (whether nominal, prepositional, or adjectival) also allow complementation with finite or nonfinite clauses. Alongside phrasal complementation like *Alice wanted a holiday* or *Alice realized her mistake,* verbs like *want, anticipate,* or *realize* also permit clausal complementation as in (54), (55), and (56) respectively:

(54a) Alice wanted to go to Switzerland.
(54b) Alice wanted Angela to go to Switzerland.

(55a) Alice anticipated going to Switzerland.
(55b) Alice anticipated Angela('s) going to Switzerland.

(56a) Alice realized that she had made an error.
(56b) Alice realized how she had gone wrong.

It is part of the valency of the verb *want*, as shown by (54), that it can occur with an elaborator in the form of an infinitive clause (54a), with the further possibility (54b) of specifying a different subject (here *Angela)* for this infinitive. The verb *anticipate*, on the other hand, though impossible with the infinitive, is natural with a gerund construction, as in (55a), and it may have a different subject specified either with a plain noun phrase (*Angela*) in informal English or with a possessive noun phrase (*Angela's*) in formal English. The verb *realize* is impossible with both infinitive and gerund but does occur with a finite clause, either declarative as in (56a) or interrogative as in (56b), although some verbs prefer either the one or the other (e.g., *admit*; *enquire*). Both nonfinite and finite clausal complementation can be regarded as cases of 'embedding,' that is, downgrading of a sentential structure to play a lower level role as a verb elaborator. Some verbs are restricted to clausal complementation: the verb *condescend,* for instance, always requires a following infinitive.

Verbs need to be lexically specified for the types of clausal elaborator they accept, and this requirement involves a number of factors. A first point is the possible verb-form in the embedded clause, i.e., whether it is an infinitive, a gerund, or a finite verb, allowing for the fact that some verbs permit two, or even (as in the case of the verb *intend*) all three of these verb forms. A second consideration is the question of a subject for this verb in the elaborator clause. Finite clauses always have an overt subject, but in a nonfinite clause, a subject may be required, permitted, or impossible, cf.

1. impossible subject, e.g., *Alfred offered (*me) to open the meeting.*
2. permitted subject, e.g., *Alfred intended (me) to open the meeting.*
3. required subject, e.g., *Alfred caused me to open the meeting.*

Nonfinite clauses without an overt subject are understood to have the same subject as the preceding verb.

A noun phrase preceding an infinitive or gerund clause elaborator may therefore be the subject of the verb, but it does not have to be. In fact, there are three possibilities for a noun phrase intervening between the main verb and an elaborator infinitive:

1. the (indirect) object of the first verb, with no connection with the second verb, e.g., *Alice promised me to open the meeting.* (This construction in English seems to be limited to the verbs *promise* and, in one particular use, *ask*.)
2. the object of the first verb and simultaneously the subject of the second verb, e.g., *Mary persuaded me to open the meeting.* (Cf. the impossibility of **Mary persuaded the meeting to be opened by me.*)
3. the subject of the second verb, with no relation to the first verb, e.g., *Mary wanted me to open the*

meeting. (Cf. the virtually synonymous passivized *Mary wanted the meeting to be opened by me*.)

A further complication involves the precise status of the subject of the finite verb. Consider the examples:

(57) Alfred hoped to entertain the audience.

(58) Alfred happened to entertain the audience.

Sentence (57) is similar to (54a), but (58) is rather different in that, although apparently the subject of the verb *happen* is simply *Alfred*, it seems semantically more appropriate to identify the subject as the whole discontinuous infinitive clause *Alfred … to entertain the audience* (cf. the sentence *It happened that Alfred entertained the audience*). It is often suggested, for instance, by Huddleston and Pullum (2002: 1194–1198), that such sentences should be described as having a 'raised' subject, in the sense that the noun phrase *Alfred* has apparently been extracted out of its position of subject of the nonfinite verb *entertain* and superficially promoted to the level of subject of the main clause verb *happen*. One problem with this analysis is that it seems to assume that the embedded clause *Alfred to entertain the audience* would naturally occur in a position after the main verb *happen*, which is not the typical position for the subject. Another approach is to regard (58) as involving a kind of compound verb *happen to entertain*, in which *entertain* is the semantic head, but *happen* is the syntactic main verb.

Something similar is found in the following:

(59) It seems/seemed that the pianist entertained the audience.

On the face of it, such a sentence looks like a case of extraposition, i.e., a structure formed when a clausal subject is replaced by *it* and postponed till the end of the sentence (as in *It annoyed me that he left early*). But an 'unextraposed' version of this sentence is ungrammatical:

(59x) *That the pianist entertained the audience seemed.

Sentences like (59) may therefore have to be regarded as an additional sentence pattern, requiring an empty *it* subject and an obligatory *that*-clause. After all, empty *it*-subjects of a different kind are required anyway for meteorological verbs like *rain* (see the section 'Levels of Analysis').

Finally, all the above points concerning verbs with embedded clauses as elaborators apply equally to adjective and noun complementation, as these phrases show:

able to speak French, capable of speaking French, confident that she could speak French; a tendency to speak French, a habit of speaking French, the fact that she spoke French.

The Limits of Valency

Verbs, adjectives, and nouns are the three major lexical word classes for which the concept of valency is clearly appropriate and for which detailed language studies have been made and preliminary dictionaries compiled. An important issue is whether the concept be extended further, beyond the occasional adverb directly derived from an adjective and copying its valency (e.g., *independently of Alfred)*. Transformational grammarians have suggested grouping together spatiotemporal adverbs and prepositions respectively as intransitive and transitive particles (or 'prepositions' in a new sense), transitive ones involving complementation with noun phrases and prepositional phrases. This insight could be applied to valency to give a classification something like the following particles (or 'prepositions' in a broader sense):

1. *zero-valent:* nearby, home; soon, previously
2. *monovalent* (obligatory simple object): at, to, from, towards; during
3. *monovalent* (omissible simple object): in, above, off; after, before
4. *monovalent* (omissible prepositional object): out (of), in front (of)
5. *bivalent:* between (… and …)

But there are problems with such an analysis: for instance, whether the situated entity (the subject or object of the sentence) should be included as a further elaborator, thus increasing all the above valencies by one; whether *out of* (or *away from*) really contains two words of the same word class particle/'preposition' (albeit of different subclasses); whether *above* and *out* (etc.), in their unaccompanied uses always imply an omitted object.

Although the application of valency grammar can thus be extended, it is not really intended to account for the whole of a syntactic system, any more than Fillmore's 'case grammar' (*see* **Case Grammar**). Valency is a matter of the subcategorization of lexical categories, and therefore in a strict sense would exclude:

1. coordinate structures, which are treated separately both by Tesnière (under the heading of the French term *jonction*)and by Hudson in his *Word grammar* (where they are basic and not derived from word-word relations)

2. grammatical 'specifiers,' such as auxiliaries and (nonpossessive) determiners, which although treated as dependents (or even governors) by many dependency grammarians, were regarded by Tesnière as involving a different relationship to main verbs and nouns respectively – a view still valid today
3. 'subordinators' in Tesnière's interpretation, which embraced prepositions and subordinating conjunctions, these being for him convertors (French *translatifs),* of noun phrases or clauses to adverbial or adnominal function, e.g., adverbial *(Alfred arrived) before the concert/before I arrived;* adnominal *(Alfred liked the book) in the window/which he'd seen in the window)* – again a theoretically tenable position.

Valency can thus evidently be included in a dependency grammar; for Engel (1977: 116), in fact, valency is simply a matter of dependency on subclasses. Equally valency can be incorporated into a functional grammar or a functionally enriched constituency grammar, albeit under a different rubric. Furthermore, valency characteristics have, in recent years, increasingly been incorporated into dictionary entries, and improved specialist valency dictionaries are being prepared (for instance, the Augsburg project for English, initiated by T. Herbst and D. Heath). For a number of years now, too, language departments of the University of Ghent have collaborated in the Contragram Group, which is currently compiling a contrastive valency dictionary. Similar projects have also been at work in China, Denmark, Japan, Korea, and Spain, just to mention some found on an Internet search. Abel *et al.* (2003) discussed the issues involved in specifying verb valency in an electronic learner's dictionary. Such ongoing work makes it clear that, despite any theoretical differences within valency theory or beyond it, its concepts are as valid as ever today. Valency relationships must find a place in every complete grammatical description.

Valkhoff, Marius François (1905–1980)

J Noordegraaf, Amsterdam, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

Marius Valkhoff, born in Zwolle, the Netherlands, in 1905, was the son of Pieter Valkhoff, a professor of French language and literature at the university of Utrecht. He studied Romance language and literature in Amsterdam, studied Italian in Florence, sojourned in Paris (1927), and studied the Rumanian (Romanian) language at Cluj, Rumania. As a student he was most interested in avant-garde movies and was a cofounder of the Dutch *Filmliga* ('movies league'). In 1931, he defended his Ph.D. thesis, entitled 'Les mots français d'origine neérlandaise,' at the University of Amsterdam. The same year saw him appointed as an acting professor of French and Italian at Stellenbosch University in South Africa, where among other things he learned how to play golf. In 1932, he was admitted as a 'privaatdocent' (external unsalaried lecturer) in Rumanian language and literature at his alma mater, opening his courses by giving a public lecture on 'Latin, Romance, Rumanian'; he thus introduced the scientific study of Rumanian in the Netherlands. One year later he was appointed to a special chair of Romance linguistics as the successor to J. J. Salverda de Grave; his inaugural lecture dealt with "argot and thieves' slang." In 1938, he was appointed full professor at the same university. From 1951, he was a professor of French and head of the Department of Romance Studies at the University of Witwatersrand, South Africa. He was the cofounder of the Ernest Oppenheimer Institute of Portuguese Studies and reintroduced the study of Portuguese into the university curriculum. Having retired in 1975, he moved on to Sauve in Languedoc, France; he died in Paris in 1980.

Valkhoff was a prolific author who published on a great variety of subjects, including theology and parapsychology (*On the edge and beyond: three essays on parapsychology*, 1957). In the early 1960s he became fascinated by creolistics. Specializing in this field of research, in the line of the great Romance scholar Schuchardt (*see* **Schuchardt, Hugo (1842–1927)**), he visited the Cape Verde Islands and the isles in the Gulf of Guinea, where creolized Portuguese was still in use. The results of his on-site research, in particular on Sao-Thomé, can be found in the various studies he published on Portuguese creoles and Afrikaans.

Studies in Portuguese and Creole, with special reference to South Africa (1966) and *New light on Afrikaans and Malayo–Portuguese* (1972) stand out as his most important works.

His 1966 book aimed at the vindication and elaboration of Hesseling's (*see* **Hesseling, Dirk Christiaan (1859–1941)**) views on the historical development of the Afrikaans language, views that had been much debated in South Africa in the first decades of the 20th century. According to Valkhoff, it was not Malay, as Hesseling had assumed, but a creolized Portuguese that was the lingua franca spoken at Cape of Good Hope when the first Dutchmen landed there in the 17th century. He claimed that the process of creolization, which was prompted by the 'linguistic encounter' of Dutch and this lingua franca, came up among the nonwhite inhabitants at the Cape. Carefully distinguishing, unlike Hesseling, between various varieties of Creole, Valkhoff also took into account "the possible influence of Khoi" (Gilbert, 1994). As creolization did not make further progress, Afrikaans did not become a true creole language; it can rightly claim the rank of a standard language. To be sure, just like Hesseling, 'the unbiased scholar,' Valkhoff held Afrikaans in high esteem.

In the days of apartheid, most of Afrikaans scholarship was not amused being told by a Hesseling redivivus (cf. Raidt, 1994 on the "new topicality of an ancient controversy") that Afrikaans might be a 'mixed' language. In addition to that, Valkhoff accused his fellow linguists in no uncertain terms of 'diachronic purism,' 'albocentrism,' and 'compartimentage.' As Roberge (1990: 133) explains, Valkhoff was of the opinion that Afrikaner scholars "had imputed their ideal of racial purity into history and linguistics." Understandably, the creolization model did not attract them very much, wishing to "see their language white and pure like their race," as Valkhoff himself put it. Secondly, Afrikaner scholars appeared to him to have confined themselves to the study of the language of the *blankes*. As to 'compartimentage,' Valkhoff was of the opinion that his colleagues had dealt with the Dutch of Europeans, Khoikhoi, and slaves as separate phenomena. All in all, Valkhoff's studies provoked a bitter and lengthy debate. It is true to say that the Romance scholar Valkhoff showed a lack of acquaintance with Germanic studies, in particular with the development of the Dutch language (Zaalberg, 1970), and the same has been argued with regard to his knowledge of Afrikaans (Raidt, 1994: 36). As one of his critics (Lubbe, 1974) put it, Valkhoff has ensured that his name will always be mentioned when the problems surrounding the origin of Afrikaans are discussed. Be this as it may, his works have stimulated the discussion concerning the question of what counts as a creole language.

Van Name, Addison (1835–1922)

G T Childs, Portland State University, Portland, OR, USA

© 2006 Elsevier Ltd. All rights reserved.

Addison Van Name's contribution to linguistics was pioneering and historically significant, but his most important legacy may not have been in linguistics. During the latter half of the 19th century, Van Name transformed the Yale library into one of the great reference libraries of the world in terms of both its organization and its acquisitions. He brought the same skills of organization and thoroughness to his work in linguistics, which, although limited, was prescient and insightful.

Van Name published on the linguistics and literatures of such diverse languages as Arabic, Japanese, and Chinese, but his contribution to modern linguistics was most important in terms of a relatively short treatise he published on several creole languages spoken in the Caribbean (Van Name, 1869–1870). Van Name was one of the earliest to recognize that creoles were qualitatively different from other languages, a distinct type, and in this article he anticipated much in the current debates on the origin and nature of creole languages.

Van Name was born to a farming family with lumber and shipping interests in Chenango, New York, on November 15, 1835. He studied at the Binghamton Academy and Phillips Andover Academy before enrolling in Yale College in 1854, where he graduated as valedictorian four years later. Studying philology (the precursor of modern linguistics), Van Name did particularly well in Hebrew. Josiah Willard Gibbs, Sr., professor of sacred languages, remarked his success and often invited him to his campus home, where Van Name became friends with his son Josiah Willard Gibbs, Jr., who pursued an academic career as a theoretical physicist. Van Name's association with Yale and closeness to the Gibbs family continued throughout his life.

After several years of travel and study in Europe, Van Name returned to Yale, first as a tutor and then as an instructor in Hebrew at the Divinity School. He switched to the position of librarian of Yale College in 1865, which he held until his retirement in 1904. In 1867, Van Name married Julia Gibbs, the daughter of his teacher Gibbs *père* and the sister of his good friend Gibbs *fils*. His close bonds to the Gibbs family were underscored when the newlyweds moved into the Gibbs household and raised their three children there. It was perhaps because of this very settled domestic scene that Van Name was able to contribute to linguistics, despite his prodigious contributions to the building of the library at Yale.

In the standard reference on pidgin and creole languages (Holm, 1988, 1989), Holm quotes approvingly an evaluation of Van Name's 1869–1870 'Contributions to creole grammar' as representing the beginning of the scientific study of creole languages (Stolz, 1986: 14). Although not terribly expansive on the theoretical side, the study clearly anticipates the central issues in creole studies and adopts a

Addison Van Name's contribution to linguistics was pioneering and historically significant, but his most important legacy may not have been in linguistics. During the latter half of the 19th century, Van Name transformed the Yale library into one of the great reference libraries of the world in terms of both its organization and its acquisitions. He brought the same skills of organization and thoroughness to his work in linguistics, which, although limited, was prescient and insightful.

Van Name published on the linguistics and literatures of such diverse languages as Arabic, Japanese, and Chinese, but his contribution to modern linguistics was most important in terms of a relatively short treatise he published on several creole languages spoken in the Caribbean (Van Name, 1869–1870). Van Name was one of the earliest to recognize that creoles were qualitatively different from other languages, a distinct type, and in this article he anticipated much in the current debates on the origin and nature of creole languages.

Van Name was born to a farming family with lumber and shipping interests in Chenango, New York, on November 15, 1835. He studied at the Binghamton Academy and Phillips Andover Academy before enrolling in Yale College in 1854, where he graduated as valedictorian four years later. Studying philology (the precursor of modern linguistics), Van Name did particularly well in Hebrew. Josiah Willard Gibbs, Sr., professor of sacred languages, remarked his success and often invited him to his campus home, where Van Name became friends with his son Josiah Willard Gibbs, Jr., who pursued an academic career as a theoretical physicist. Van Name's association with Yale and closeness to the Gibbs family continued throughout his life.

After several years of travel and study in Europe, Van Name returned to Yale, first as a tutor and then as an instructor in Hebrew at the Divinity School. He switched to the position of librarian of Yale College in 1865, which he held until his retirement in 1904. In 1867, Van Name married Julia Gibbs, the daughter of his teacher Gibbs *père* and the sister of his good friend Gibbs *fils*. His close bonds to the Gibbs family were underscored when the newlyweds moved into the Gibbs household and raised their three children there. It was perhaps because of this very settled domestic scene that Van Name was able to contribute to linguistics, despite his prodigious contributions to the building of the library at Yale.

In the standard reference on pidgin and creole languages (Holm, 1988, 1989), Holm quotes approvingly an evaluation of Van Name's 1869–1870 'Contributions to creole grammar' as representing the beginning of the scientific study of creole languages (Stolz, 1986: 14). Although not terribly expansive on the theoretical side, the study clearly anticipates the central issues in creole studies and adopts a

refreshingly modern perspective for the period in which he was writing.

Van Name's study is based primarily on written works and primarily on French creoles: "The survey includes five dialects of the French Creole and the Spanish, to which I have added for the sake of comparison brief notices of the Dutch Creole, and the Negro English of Surinam" (Van Name, 1869–1870: 126). He also benefited from the knowledge of several 'native' speakers to supplement these written works. The study is first of all important in adopting a **comparative** approach and generalizing about creoles *vis-à-vis* each other. He was the first to note similarities across creoles in terms of their phonology, morphosyntax, and even lexicon.

Previous studies and many subsequent ones based themselves on comparisons between a creole and its (European) lexifier language, i.e., the language that provided the creole's vocabulary. These latter studies usually took the position that the creole was a debased form of the lexifier, a position Van Name explicitly rejected.

Van Name looked forward to variationist approaches in recognizing the patterned variation present in creoles and its source, again providing a refreshing counterpart to the generally negative evaluation of creoles:

> . . . the [continued] contact with French, which has never entirely ceased, has been a disturbing influence and a source of corruption, for the standard of Creole purity is to be sought at the furthest remove from the French, where the Creole tendencies are the most developed.

Here Van Name anticipates the notion of the creole continuum and polylectal grammars found in the creolist literature of the 1970s.

Coupled with these insights was Van Name's perspective on seeing creoles as **creative** adaptations with limited resources: "we find, if not many new formations, numerous instances of old material put to new uses" (Van Name, 1869–1870:123). Van Name further recognized that the originators of a creole were typically adults whose ears and tongues had already accustomed themselves to another language under unusual sociohistorical circumstances.

Another way in which Van Name's contribution was important was in recognizing that the processes involved in creole formation are common elsewhere in language change. In a relatively modern way he saw the birth of a creole as telescoping the processes that affect all languages: "here two or three generations have sufficed for a complete transformation" (Van Name, 1869–1870: 123).

Van Name was also right in stating that creoles were not a simple mix of an African and a European language: "It is scarcely necessary to remark that these languages are not of mixed blood, half African and half European, for languages do not mingle so readily as races" (Van Name, 1869–1870:123). His study is also important in remarking the African contribution to creoles, although he saw it as being rather limited, i.e., to the phonology. A weakness that is also found even in more recent work proceeds from an ignorance of African languages (he calls them collectively "African," as if African languages constituted some monolithic entity). Nonetheless, it is the regret of later linguists that Van Name had to spend so much time building the Yale library, for surely his continued focus on creole languages and linguistics in general would have benefited the field.

Vanuatu: Language Situation

R Early, University of the South Pacific, Port Vila, Vanuatu

© 2006 Elsevier Ltd. All rights reserved.

Vanuatu is a Melanesian micro-state in the southwest Pacific, renowned for its high density of small vernacular languages and complex sociolinguistic situation. The country's colonial history as a jointly-administered British and French condominium until independence in 1980 shaped the modern language environment. English and French are both official languages, and there is a dual stream anglophone and francophone education system. Another colonial legacy is the pervasive presence of Bislama, an English-lexifier contact language given special constitutional status as both the sole national language and a third official language. Vanuatu is a least developed country of only 200 000 inhabitants, and this configuration of administrative languages adds both color and cost to its governance.

Further complexity arises from the vernacular language situation, truly exceptional in world terms. The most recent survey (Lynch and Crowley, 2001) details 98 distinct vernaculars, 81 of which are still actively spoken, while 17 are moribund. Thirteen languages have over 5000 speakers, giving the other 85 an average size of 1000 speakers. Most vernaculars (75%) are not well known to the linguistic community, appearing in the literature with a short word-list or less.

Vanuatu's extreme linguistic speciation is regarded as a national treasure, 'cherished' in the constitution. It arose from pre-contact settlement patterns whereby small clans were dispersed over rugged terrain and divided by rough seas. The resulting complex of subgroups and dialect chains is still being unraveled. In post-contact times, introduced diseases, genocidal acts, and the labor trade led to severe depopulation, social dislocation, and linguistic decline and extinction. The vernaculars are Oceanic (Austronesian family) languages probably descended from a single ancestral language that arrived about 3500 years ago as so-called Lapita people expanded southeast into the Pacific from Papua New Guinea through the Solomon Islands. Later, founder communities spread from Vanuatu to Fiji and Polynesia, to New Caledonia, and possibly to Micronesia.

Multilingual repertoires are the norm, and language issues are prominent in national life. The relative influence of French and English is a political concern, and suggestions that French might be waning are countered with appeals to misunderstood language equity provisions in the constitution. The judicial system has operated in English since independence, but there are plans to transform it into a dual-language operation. Significant language planning matters include the need for standardization and intellectualization of previously maligned Bislama as it rapidly creolizes in urban settings, and also the protection and development of vernacular languages in the face of potential widespread endangerment through shift to Bislama. A recent Education Master Plan requires that the first 3 years of basic education be conducted in the vernacular, but difficulties in developing orthographies and materials is hampering implementation, although some successful vernacular literacy projects are run by non-state actors. From 2003, an officially recognized and broadly representative National Language Committee has been advising in all language-related areas, but will always be challenged by a conundrum of competing aspirations: the desire for vernacular vitality as a source of Melanesian identity, the demand for development of Bislama as the national language, and the dictate that English and/or French proficiencies attain levels required for international interaction.

Variability in Japanese (Discourse)

S Okamoto, California State University, Fresno, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

The characterization of Japan as a homogeneous society is a common cultural stereotype. In reality, considerable diversity exists in its ethnic, social, and linguistic makeup. Linguistically, although Japanese is the dominant language, speakers of minority languages cannot be ignored. Minority groups in Japan (as of 2001) include approximately 600 000 resident Koreans and 1.3 million foreign workers and their children from the Philippines, China, Brazil, Peru, Thailand, and other countries (Sugimoto, 2003). Many of them are bilingual. Many Japanese nationals are also bilingual, including returnees from abroad. Although Japan's language policy has been based on a monolingual assimilationist ideology (Noguchi and Fotos, 2001), the country is becoming increasingly multilingual as it seeks to adapt to globalization.

Within the Japanese language itself, extensive diversity also exists across regions, individuals, and contexts. This diversity has been the major focus of study in Japanese sociolinguistics, although scholars vary in their approaches. Many studies employ a social/situational factors approach, often based on quantitative correlational analyses; they may imply that social factors directly affect the language choice, that language choice is a straightforward reflection of the social context. On the other hand, many recent studies adopt a social constructionist approach, regarding the speaker's choice of linguistic forms as a strategy for constructing social identity and social relations. Methodologically, the majority of the studies that employ a social factors approach rely on the data drawn from self-report surveys, but some Labovian sociolinguistic variation studies are available that analyze natural speech data. With a few exceptions, studies that rely on self-report surveys tend to equate what speakers say about their language use with their actual language use without critically discussing the potential difference between the two. On the other hand, studies that take a social constructionist approach usually examine data drawn from natural speech, employing a discourse or conversation analytic method.

Regional Variation and Standardization

Dialect Divisions

Japan, a mountainous island country, is rife with dialectal variations. These variations can sometimes be so large that mutual intelligibility may be hindered. The nature of this regional variability has been extensively investigated in Japanese dialectology. Largely based on the data from self-report surveys and interviews, a number of major dialect divisions have been proposed. One major undisputed division lies between the Ryukyuan dialects and the mainland dialects, with each group being further divided into smaller dialect areas. Significant differences between the two major groups have been observed in phonological, grammatical, and lexical features, including the vowel systems (i.e., three short vowels *a, i, u* in the Shuri variety of the former = Ryukyu vs. five short vowels *a, i, u, e, o* in most varieties of the latter = mainland); the consonantal systems (e.g., glottalized phonemic initial consonants in some varieties of the former but not in the latter); inflections of verbs and adjectives (e.g., distinction between the conclusive form and the attributive form of verbs and adjectives in the former but not in most varieties of the latter); and lexical items (e.g., *wan* vs. *watashi* 'I').

The mainland dialects are sometimes further divided into three areas: eastern Japan, western Japan, and Kyushu. However, another classification recognizes only two areas in the mainland: eastern Japan and western Japan (Kyushu being included in the latter), based on the existence of a major division, or

On the other hand, studies that take a social constructionist approach usually examine data drawn from natural speech, employing a discourse or conversation analytic method.

Regional Variation and Standardization

Dialect Divisions

Japan, a mountainous island country, is rife with dialectal variations. These variations can sometimes be so large that mutual intelligibility may be hindered. The nature of this regional variability has been extensively investigated in Japanese dialectology. Largely based on the data from self-report surveys and interviews, a number of major dialect divisions have been proposed. One major undisputed division lies between the Ryukyuan dialects and the mainland dialects, with each group being further divided into smaller dialect areas. Significant differences between the two major groups have been observed in phonological, grammatical, and lexical features, including the vowel systems (i.e., three short vowels *a, i, u* in the Shuri variety of the former = Ryukyu vs. five short vowels *a, i, u, e, o* in most varieties of the latter = mainland); the consonantal systems (e.g., glottalized phonemic initial consonants in some varieties of the former but not in the latter); inflections of verbs and adjectives (e.g., distinction between the conclusive form and the attributive form of verbs and adjectives in the former but not in most varieties of the latter); and lexical items (e.g., *wan* vs. *watashi* 'I').

The mainland dialects are sometimes further divided into three areas: eastern Japan, western Japan, and Kyushu. However, another classification recognizes only two areas in the mainland: eastern Japan and western Japan (Kyushu being included in the latter), based on the existence of a major division, or

a bundle of isoglosses, between the two along the Japan Alps that runs through the central region of the mainland. The well-known linguistic differences between eastern and western Japan include phonological differences (e.g., pitch-accent patterns), morphosyntactic features (e.g., imperative verb forms *-ro* vs. *-i/-yo*; copulas *da* vs. *ja/ya*), and lexical items (e.g., *iru* vs. *oru* 'exist'; *shoppai* vs. *karai* 'salty').

The major dialect divisions just discussed are based on the differences in overall linguistic aspects, including phonology, grammar, and lexicon. Other divisions have also been proposed based on a particular aspect, such as accentual systems, segmental features, or lexical items. For example, five groups are generally recognized on the basis of accentual systems: Kyoto-Osaka (with a four-way contrast in three-mora phrases), Tokyo (with a three-way contrast), Kagoshima-Nagasaki (with a two-way contrast), Miyakonojo (one-pattern), and part of Tohoku/Kyushu (accentless) (see Kokugo-gakkai, 1973; Sanada, 2002; Shibatani, 1990 for delineations of Japanese dialects).

Standardization and Code Switching/Style Shifting

The traditional classification of regional dialects outlined may suggest that the boundaries between different dialects are clear-cut and undisputed. However, in reality, the differences are on a continuum, both synchronically and diachronically. A particularly important issue to consider in this respect is the rapid advancement of standardization of Japanese. Due to a variety of factors associated with the nation's modernization since the Meiji Restoration in 1867 (e.g., the government language policy, which promoted Standard Japanese, or the speech of "the educated Tokyoites," particularly up until the end of World War II, and the development of mass communication and transportation system) language standardization has been steadily advancing in modern Japan, reducing regional differences (e.g., Kobayashi *et al.*, 1996; Chapter 10 in Kunihiro *et al.*, 1999; Sanada, 2002). Consequently, even in the same area there is wide interspeaker (especially intergenerational) and intraspeaker variation in the use of the regional dialect (see following). In other words, the linguistic composition of regional Japan is much more complex than the regional dialects delineated in traditional dialectology, which tends to represent older linguistic forms.

Most of the studies that report the advancement of standardization are based on apparent-time studies. For example, a number of apparent-time studies indicate that younger generations use certain lexical items and honorific morphemes in Standard Japanese more frequently than older generations (Inoue, 1989; Kobayashi *et al.*, 1996; Sanada, 2001, 2002). Real-time studies are rare in Japanese sociolinguistics (as well as in sociolinguistics in general). One notable real-time study, however, was conducted by the National Language Research Institute, which carried out dialect surveys in Tsuruoka, a small city in northern Japan, at 20-year intervals in 1950 (with 577 informants), 1971 (with 564 informants), and 1991 (with 719 informants). Yoneda (1997) reported the results concerning two phonological aspects: segmental features (e.g., labialization of *k*, voicing of intervocalic consonants in Tsuruoka) and accentual patterns (e.g., LH, as in *nego* 'cat', in Tsuruoka vs. HL, as in *neko*, in Standard Japanese). They show that standardization has been proceeding steadily in both phonological aspects, especially in the segmental features, which were found to be completely standardized in the younger age groups during the 1991 assessment (see also Chapters 11 and 20 in Kunihiro *et al.*, 1999). Note, however, that since these findings are based on interview data, the degree of standardization, especially in informal speech, may not be as high as these results indicate.

Although it is evident that the standardization of Japanese has been advancing steadily, its effects may vary depending on the dialect (Sanada, 2002). For example, the Kansai dialect is often said to have the greatest vitality because of the large number of speakers and their pride in their dialect (Inoue, 1989). It has also been claimed that despite the advancement of standardization, regional varieties have not lost their vitality, based on the following two kinds of phenomena. One is the fact that the so-called *shin-hoogen,* new dialect forms – forms that are not standard and used by younger generations more frequently than older generations (e.g., the morpheme *-be* "isn't it?" in eastern Japan, the negative past tense form of a verb *-n katta* in western Japan) – have been constantly emerging in regional dialects, indicating that the direction of language change is not uniquely toward standardization (Inoue, 1989, 1998); instead, more complex processes of dialect leveling are taking place. In addition, many speakers are now said to be bidialectal and use regional and Standard Japanese differentially, depending on the context. Further, it has been claimed that speakers also use a *neo-hoogen,* neo-dialect, a variety in between those two varieties (e.g., Kobayashi *et al.*, 1996; Sanada, 2001, 2002). Although these studies are mostly based on self-report surveys or informal observations, some of the recent studies have begun to analyze actual conversations. Okamoto (2004), for example, demonstrates that speakers do not code-switch between two or three varieties as distinct linguistic systems, and that the use of regional and standard variant forms is a matter of degree created strategically by the complex admixture of (phonological, morphological, and lexical)

variants inter- and intrasententially. Whether or not it is considered a matter of degree, the differential use of regional and Standard Japanese is generally viewed as involving a style shift according to the formality of the situation. In other words, regional dialects are no longer simply linguistic systems associated with different geographical areas but they also function as an index of a speech style concerning formality.

Social Identity and Interspeaker Variation

Variation in Japanese linguistic practice may also concern the speaker's social identity as it relates to gender, age, class, and other attributes. This variation has been another major focus of investigation in Japanese sociolinguistics.

Gender

Until recently, research on Japanese language and gender, a widely studied topic, has focused on the description of gender differences in speech patterns. Based on the assumption that Japanese men and women use distinct 'languages,' or 'men's language' and 'women's language', the differences between the two have been characterized in terms of both general stylistic characteristics, such as polite, gentle, and empathetic, and specific linguistic forms (usually in Standard Japanese), such as self-reference terms (e.g., feminine form *atashi*; masculine forms *boku* and *ore*), address terms (e.g., masculine forms *omae, kimi*), sentence-final particles (e.g., feminine forms *kashira* and *wa*; masculine forms *zo* and *ze*), honorifics, and pitch levels (e.g., Ide and Yoshida, 1999; Ogino *et al.*, 1985; Shibatani, 1990). With a few exceptions, these studies are largely based on researchers' casual observations or self-report surveys and are more likely to represent normative usage than actual speech practices. Further, they essentially employ a social factors approach, assuming that the use of gendered language is a straightforward reflection of the speaker's gender.

In recent years, however, researchers have begun to examine real speech data closely, while at the same time examining the historical process of the societal norm construction for women's speech and its implications (e.g., Nakamura, 2001; Okamoto and Shibamoto Smith, 2004). In general, these studies demonstrate that although the norms may serve as constraints on women's speech, Japanese women (and men) do not necessarily conform to them and that there is wide variation related to the speaker's social background, the speech context, and the speaker's language ideology (e.g., Gendai Nihongo Kenkyukai, 1999, 2002; Okamoto and Shibamoto Smith, 2004). As in the recent gender and language research on English and other languages, the findings of these Japanese studies show that women (and men) do not form a homogeneous speech group, and that gender cannot be treated as a variable that determines one's speech independently of other social variables such as age, class, and sexuality.

One aspect of the intragender variability concerns age differences. It has been reported that (among female speakers of Standard Japanese) younger women tend to use stereotypically feminine forms less frequently than older generations, although even the latter's use of such forms is not particularly pervasive (see following). Moreover, variation has been observed even within the same age group. Miyazaki's (2004) ethnographic study of the speech of junior high school students, for example, shows that not all the girls in the same year use stereotypically feminine self-reference terms, and that girls that belong to a nonconformist group use most untraditional terms (i.e., the stereotypically masculine terms *ore* and *boku*). Another aspect of the intragender variability concerns occupation or social class. For example, Gendai Nihongo Kenkyukai (1999) reports that analyses of women's speech at 19 workplaces show that women used gender-neutral sentence-final forms most frequently, that they hardly used stereotypically feminine sentence-final forms and self-reference terms (*watakushi* and *atashi*), and that they often did not use (expected) honorifics.

As indicated by the preceding discussion, the main focus of Japanese language and gender research has centered on women's speech. Only recently has attention begun to be paid to the variability in men's speech. Gendai Nihongo Kenkyukai (2002), for example, reports that men observed in 21 workplaces hardly used stereotypically masculine sentence-final particles (e.g., *zo* and *ze*), while using honorifics frequently, and also that there is wide variation within men's speech, as illustrated by the use of masculine terms *boku* and *ore*, the former being used frequently at universities and schools and not at other workplaces (e.g., companies), where *ore* is used much more commonly (see also Miyazaki, 2004).

The relation of language, gender, and sexual orientation is another area that has recently begun to receive researchers' attention. Several studies show how gays and lesbians use or disuse gendered speech styles strategically to construct their identity in their struggle with hegemonic heterosexual gender norms (Maree, 2002; Chapters 5, 6, and 11 Okamoto and Shibamoto Smith, 2004). One other important topic that is beginning to gain attention is gender in regional dialects, whereas previous studies have concentrated on Standard Japanese. It has been noted that gender differences in speech are relatively small in regional dialects.

For example, in northern regions some women use the 'masculine' *ore* regularly. Only a few studies have started investigating if and how gender is relevant to speakers of regional dialects.

Although the wide within-gender variability has been demonstrated by recent research, it does not mean that gender *per se* is irrelevant. Studies that compare real speech patterns of women and men report gender differences in the use of certain linguistic forms (e.g., the use of *boku* and *ore* is not common among adult [heterosexual] women) suggesting that speakers are constrained by the gender norms (Gendai Nihongo Kenkyukai, 1999, 2002). Researchers have therefore begun to consider how and why speakers choose their speech styles vis-à-vis their conceptions of language and gender norms.

Age

Age difference also affects Japanese language practice. Linguistic features that have been studied in relation to age include accentual patterns, morphological features (e.g., verb inflections, honorifics, sentence-final particles), and lexical items (e.g., *shin-hoogen* 'new dialect forms', and slang). Many of these studies investigate the phenomena that involve change in progress, although they are generally apparent-time studies. There are also studies of variation related to age grading.

As noted earlier, age difference has been widely investigated with regard to the standardization of Japanese; it has been observed in many regions of Japan that Standard variants as opposed to regional variants as well as *shin-hoogen* 'new dialect' forms are used more frequently by younger generations than older generations. Studies also have observed age differences with regard to some features of Tokyo Japanese, in which younger speakers use innovative forms more frequently than older speakers (Hibiya, 1995; Inoue, 1989, 1998; Matsuda, 1993). Most of these studies interpret the age difference in their apparent-time data as a reflection of the change in progress in real time and explain the change in terms of both language internal and external factors. For example, analyzing the distribution of the denasalization of the velar nasal in the natural speech data drawn from Labovian sociolinguistic interviews involving 62 speakers in Nezu, Tokyo, Hibiya (1995) found that younger speakers used the innovative form [g] (instead of [ŋ]) much more frequently than older speakers, and further that other social factors (e.g., place of birth in Tokyo) as well as language internal factors (e.g., morpheme boundary) also affected the distribution. Matsuda (1993), another variation study, examined natural speech data with regard to the use of the simplified verb potential form *-reru* rather than *-raresu* in Tokyo Japanese; he found an age stratification in the use of this variable and explained the change in terms of a number of language internal factors (e.g., length of the stem) and external factors (e.g., gender).

Variability may also involve age grading. As mentioned earlier, younger women have been found to use stereotypically feminine forms less frequently than older women. This finding, based on apparent-time data, does not necessarily mean that Japanese women's speech has been defeminized over time. It may also be a reflection of age grading within each speaker – an issue that cannot be resolved in the absence of real-time studies. With regard to age grading, some researchers have also examined the so-called *wakamono-go* youth language, or in-group expressions/slang. These expressions are profuse and constantly being renewed. Based on a survey of college students, Yonekawa (1998) discussed the word formation process of these new expressions as well as their functions (e.g., to index group solidarity, to enjoy word play; see also Chapter 19 in Kobayashi *et al.*, 1996). Age grading has also been investigated in relation to language socialization of Japanese children. Studies have examined how children learn to use a variety of linguistic features that are indexical of sociopragmatic meanings (e.g., directives, honorifics, back channels). The acquisition of honorifics, for example, has been discussed by several studies, which indicate that compared to the use of referent honorifics, that of addressee honorifics is learned much earlier, that is, by the age of three (e.g., Fukuda, in press).

Social Class

Social class may also affect Japanese language practice. In Japanese sociolinguistics the notion of class has generally been used rather informally in relation to more specific variables, such as occupation, place of residence, or education (but cf. Chapter 8 in Kunihiro *et al.*, 1999). Thus, for example, it is said that the use of honorifics is related to social class based on the findings such as follows: surveys conducted in northern Japan in the 1970s indicate that the higher the speaker's education, the greater the use of honorifics; the office workers living in cities use honorifics more than farmers and fishermen living villages (Inoue, 1989). Differences in speech patterns have also been observed between the Yamanote 'the hillside' and Shitamachi 'the downtown' areas in Tokyo, which many perceive as a class difference. For example, speakers from Yamanote use the [g] variant of the velar nasal more frequently than those from Shitamashi (Hibiya, 1995; see also Chapters 6 and 7 in Kunihiro *et al.*, 1999 for honorific use in the two areas). Further, some studies examine the correlation

between a linguistic variable and speaker's occupation (or place of residence or education) without explicitly regarding it as a class difference. Gendai Nihongo Kenkyukai (2002), for example, found that the use of certain linguistic features varied depending on the type of workplace; for example, an office of a music band used formal expressions (honorifics and formal address terms) infrequently, compared to other offices and schools (see also the earlier discussion of the masculine self-reference pronouns *ore* and *boku*).

In sum, studies have shown that although a variety of social variables, such as gender, age, and class, affect choice of linguistic forms, they usually interact with each other and jointly influence the choice rather than as independent variables. Note also that most of the studies have employed a social factors approach, whereas some recent studies (particularly in the area of language and gender) have adopted a social constructionist approach.

Conversational Context and Intraspeaker Variation

There is also wide intraspeaker variation in Japanese. That is, speakers change their speech style according to the features of the context, including the interpersonal relationship between the speaker and the addressee or referent, setting, speech act type, and genre. Many linguistic features can affect a particular speech style, such as honorifics, address and reference terms, lexical items, (in)direct speech, discourse markers, and Standard/regional Japanese. These features are often discussed as involving politeness and/or formality. For example, as discussed earlier, speakers use Standard and regional Japanese (in differing proportions), depending on the situation, to bring about different styles that primarily concern formality.

Honorifics

The complex honorific system, one of the most important sociolinguistic features of Japanese, has attracted great interest of scholars in Japanese traditional grammar, sociolinguistics, and discourse analysis. Most of the earlier studies rely on examples of honorifics used in isolated (and usually constructed) sentences and explain the usage based on a social/situational factors approach. Many recent studies, on the other hand, analyze the use of honorifics in actual conversations, often regarding it as a strategy.

Although the details differ, in traditional grammar, honorifics are commonly classified into two major categories: addressee honorifics (e.g., AHON in examples (1), (2), and (3)) and referent honorifics, the latter being further subdivided into subject honorifics (e.g., SHON in example (2)) and non-subject honorifics (e.g., NSHON in example (3)).

(1) ashita wa yasumi des–u.
tomorrow TOP *holiday* is.AHON-PRES
'Tomorrow is a holiday.'

(2) shachoo wa moo sore o
President TOP *already* *that* OBJ
o-yom-ini nar-imash-ita.
SHON-*read*-SHON-AHON-PAST
'The President read it already.'

(3) watashi wa sensei ni sore o
I TOP *teacher* *to* *that* OBJ
o-kaesh–ish-imash-ita.
NSHON-*return*-NSHON-AHON-PAST
'I returned that to the teacher.'

The usage of these different types of honorifics is then characterized in terms of contextual features, especially interpersonal distance. Although insightful, these characterizations are usually given without empirical data. In general, both addressee and referent honorifics are said to be used to show deference/politeness to the relevant individual (i.e., the addressee or referent), who is perceived to be distant (because of the status difference and lack of intimacy) from the speaker. Although interpersonal distance is considered most important, other factors (e.g., formality of setting, type of genre, topic, means of communication, gender) are also noted as relevant (e.g., Kikuchi, 1994; Shibatani, 1990). Most of these studies assume that honorific usage is governed by contextual factors, which tends to yield a prescriptive characterization, but some grammarians recognize strategic uses of honorifics, for example, to express a class status, to convey sarcasm (e.g., Kikuchi, 1994).

Honorific usage has also been investigated by Japanese sociolinguists. Again, many of these studies are correlational and based on large-scale self-report surveys, asking what sentences a speaker would use in different hypothetical situations (e.g., Hill *et al.*, 1986; Ogino *et al.*, 1985). They employ basically a social/situational factors approach, linking social variables (e.g., interpersonal distance, gender) straightforwardly to honorific use. Further, a number of these studies discuss honorifics as a device for expressing politeness, emphasizing that Japanese politeness is based on rigorous situation-based and socially agreed-upon rules, unlike languages such as English, where the expression of politeness is largely a matter of a speaker's strategy. Thus, once a certain situation is recognized, use of honorifics or other formal expressions is obligatory (see, for example, Hill *et al.*, 1986; Ide and Yoshida, 1999). Although

they recognize some strategic uses that deviate from the rules, these studies tend to be prescriptive, largely because self-report surveys are likely to elicit speakers' beliefs about how one should talk in certain situations.

Many recent studies, on the other hand, analyze the use of honorifics in actual discourse. These studies demonstrate the complexity and variability in honorific use that cannot be fully accounted for in terms of the situation-based normative rules (e.g., Cook, 1998; Chapter 4 in Gendai Nihongo Kenkyukai, 1999; Usami, 2002; Chapters 2, 10, and 13 in Okamoto and Shibamoto Smith, 2004). A number of studies show that a speaker often uses both addressee honorifics and plain (or nonhonorific) forms in the same conversation for a variety of reasons, including attempts to effectively carry out a particular speech act (e.g., greeting, making a request, scolding, sarcasm) or activity (e.g., classroom presentation, playing a game), to express emotions (e.g., anger, empathy), to define or change the relational context (e.g., distancing), and to present one's persona in a particular light (e.g., well mannered). For example, in a conversation between family members, plain forms are normally used, but honorifics may sometimes be used when making a request, announcement, scolding, and so on. Teachers in the classroom switch between honorific and plain forms, depending on the activity type (e.g., lecture to the whole class or individual interaction). Further, it has also been noted that speakers may not necessarily use honorifics in the same way in like circumstances because of differences in the attitudes toward the use of honorifics. These studies generally view the use of honorifics as a strategy based on the speaker's assessment of the specific context vis-à-vis the normative usage. Some studies (e.g., Usami, 2002) also attempt to account for Japanese honorific usage within the framework of universal theory of (discourse) politeness rather than regarding it as culturally specific.

Address and Reference Terms

The use of address terms also involves style shifting. Traditionally, it has been said that one uses last name + title, last name or kinship term + the polite suffix *-san*, or title for a person to whom one is expected to show respect, whereas one uses first name + the informal suffix *-chan/kun*, first name, or second-person pronoun (e.g., *anata, omae*) for an equal- or lower-status person (Ide and Yoshida, 1999). Some studies have examined the use of address terms in actual conversations. For example, Gendai-Nihongo Kenkyuukai (2002, Chapter 7) reports that the use of address terms in the 40 workplaces observed tends to conform to the common characterization summarized earlier, but at the same time there are many situational and individual variations, indicating that the choice is quite flexible. For example, speakers in some offices (e.g., a design office, a music office) used much more casual forms of address (e.g., first name only, the pronoun *omae*, last/first name + *chan*, nickname) even during business meetings, as compared to other workplaces. The same study also notes that the same speaker in the same workplace may use different address terms for the same individual in different situations, for example, a meeting or a lunch time (see also Chapters 8 and 16 in Kunihiro *et al.*, 1999 for diverse uses of address terms in a family).

Japanese also has many self-reference terms, including a number of first-person pronouns (e.g., *watakushi, watashi, atashi, boku, ore*). They are commonly associated with formality and gender. Studies based on observations of actual conversations have found that speakers may use different self-reference terms depending on the situation. Miyazaki (2004), for instance, found that boys may shift between *boku* and *ore,* depending on the interlocutor's gender and relative power. It has also been observed that gays and lesbians may shift between normative and nonnormative usage of self-referencing, depending on the interlocutor, speech act, and emotion (Chapters 5 and 11 in Okamoto and Shibamoto Smith, 2004). Gendai Nihongo Kenkyuukai (1999, 2002) also reports wide variation in the use of self-reference terms.

Genres and Speech Acts

As indicated in the preceding discussion, in addition to interpersonal relationships, genres and speech act types are important situational factors that affect speech style choice. There have been studies focused on particular genres (e.g., business meetings, debates, cooking classes, university faculty meetings, telephone conversations). Working within the framework of discourse or conversation analytic research, these studies closely examine natural speech data with regard to the use of specific linguistic features (e.g., honorifics, indirect speech, discourse markers, repetitions, sentence connectives) and strategies (e.g., be (in)direct, veil opposition) used in particular genres. Many of these studies also discuss specific speech acts (e.g., criticism, instruction, refusal, complaint), since genres are often closely related to speech acts. In particular, expressions of conflicts (e.g., disagreement, complaint) have been well studied. Despite the common cultural stereotype of Japanese as uniquely harmonious, studies have found that Japanese do express conflicts and that their expressions depend on the situational factors, including the type of genre, the relationship between the participants, and the participants' goals. For example, conflicts may be

expressed directly in televised political debates, but not in academic debates; lower-status persons may use more indirect speech than higher-status persons (e.g., Szatrowski, 2004).

Many of these studies also compare Japanese and English discourse. Mayes (2003), for example, analyzed Japanese and American cooking classes and found that compared to the American teachers, the Japanese teachers were much more formal (using honorifics) and focused only on task-oriented content, which contributed to the construction of a professional relationship between them and their students. Yotsukura (2003) examined a large corpus of Japanese business transactional telephone conversations, comparing them with English data, and found that Japanese speakers use more empathetic and indirect methods of communication in presenting problems. Many of these cross-linguistic studies resort to Japanese cultural concepts (e.g., *wa* 'harmony', *omoiyari* 'emphathy', *kikubari* 'consideration') to explain their findings, but recent studies (e.g. Mayes, 2003; Yotsukura, 2003) are increasingly more cautious about treating such cultural concepts, or ideologies, as having overarching causal effects on Japanese communication styles and attempt to seek explanations in situation-specific variables, including genres and speech acts.

Introduction

Variationist sociolinguistics in the Labovian tradition has found that apparently 'free' variation in linguistic form is actually systematically constrained by both linguistic and extralinguistic factors. That is, when a linguistic system presents multiple ways of saying the 'same' thing (different realizations of the same underlying form, presence or absence of inflectional morphology, alternative syntactic constructions), speakers' production of the alternating forms is not random, but rather correlated with both linguistic ('internal') and social ('external') factors (see Labov, 1994, 2001). The linguistic factors include aspects of all levels of linguistic structure (depending to some extent on the nature of the sociolinguistic variable in question), from phonetic context to syntactic constructions. The social factors include characteristics of speakers, relationships between interlocutors, and characteristics of social situations. Thus, sociolinguistic variation can be broadly construed to include patterns of use of honorific markers, the patterning of linguistic forms across registers or situationally based speech styles, and the choice among varying ways to encode particular speech acts.

The existence of patterns within variation across all levels of linguistic structure begs the question of how these patterns can be accommodated in models of linguistic structure. This article discusses how this problem can be approached from one particular theory of grammar, namely Head-driven Phrase Structure Grammar (HPSG; Pollard and Sag, 1994). HPSG conceptualizes language as a system of Saussurean signs. That is, words, phrases, and clauses are all pairings of form and meaning. A grammar of a language is a system of constraints on which signs are admissible, in general and as stand-alone utterances. These constraints are associated with linguistic types, which are in turn organized into a type hierarchy. HPSG signs are associated with four types of information: phonological, syntactic, semantic and pragmatic.

Taking the 'meaning' side of the form-meaning pairing as including pragmatic information as well as semantic information opens the door to modeling the relationship between linguistic form and social meaning (Eckert, 2000; Bender, 2001). In fact, Pollard and Sag (1994) discuss Korean honorifics as well as German polite plurals and model what has been called 'social meaning' as constraints within the 'CONTEXT' field. For example, a Korean noun bearing the honorific suffix *-nim* would be associated with the information that the speaker owes honor to the referent of that noun. To represent this information, the CONTEXT field contains a collection of contextual indices representing information about the speaker, addressee, spatiotemporal location, etc., and a collection of relations such as 'owe-honor' that refer to those indices. (See also Siegel, 2000, and Fukushima, 2002, for related treatments of Japanese honorifics and social role terms.) Paolillo (2000) provides a more elaborated model of registers in Sinhala.

Meanwhile, recent work in variationist sociolinguistics (developing themes introduced in Labov, 1963, and Weinreich *et al.*, 1968) has elaborated the idea that much intra- and inter-speaker variation is the result of speakers creating linguistic (and therefore social) styles out of linguistic alternatives imbued with social meaning (Eckert and McConnell-Ginet, 1992; Eckert, 2000; Irvine and Gal, 2000; Coupland, 2001). 'Social meaning', in this context, is the potential that a particular linguistic form or pattern of linguistic forms has to be used for presenting the speaker's identity, affective state or attitudes, or constructing the speech situation or relationship between the interlocutors as being of a certain type. Linguistic forms bearing social meanings are often integrally involved in the creation (and maintenance) of social

Introduction

Variationist sociolinguistics in the Labovian tradition has found that apparently 'free' variation in linguistic form is actually systematically constrained by both linguistic and extralinguistic factors. That is, when a linguistic system presents multiple ways of saying the 'same' thing (different realizations of the same underlying form, presence or absence of inflectional morphology, alternative syntactic constructions), speakers' production of the alternating forms is not random, but rather correlated with both linguistic ('internal') and social ('external') factors (see Labov, 1994, 2001). The linguistic factors include aspects of all levels of linguistic structure (depending to some extent on the nature of the sociolinguistic variable in question), from phonetic context to syntactic constructions. The social factors include characteristics of speakers, relationships between interlocutors, and characteristics of social situations. Thus, sociolinguistic variation can be broadly construed to include patterns of use of honorific markers, the patterning of linguistic forms across registers or situationally based speech styles, and the choice among varying ways to encode particular speech acts.

The existence of patterns within variation across all levels of linguistic structure begs the question of how these patterns can be accommodated in models of linguistic structure. This article discusses how this problem can be approached from one particular theory of grammar, namely Head-driven Phrase Structure Grammar (HPSG; Pollard and Sag, 1994). HPSG conceptualizes language as a system of Saussurean signs. That is, words, phrases, and clauses are all pairings of form and meaning. A grammar of a language is a system of constraints on which signs are admissible, in general and as stand-alone utterances. These constraints are associated with linguistic types, which are in turn organized into a type hierarchy. HPSG signs are associated with four types of information: phonological, syntactic, semantic and pragmatic.

Taking the 'meaning' side of the form-meaning pairing as including pragmatic information as well as semantic information opens the door to modeling the relationship between linguistic form and social meaning (Eckert, 2000; Bender, 2001). In fact, Pollard and Sag (1994) discuss Korean honorifics as well as German polite plurals and model what has been called 'social meaning' as constraints within the 'CONTEXT' field. For example, a Korean noun bearing the honorific suffix *-nim* would be associated with the information that the speaker owes honor to the referent of that noun. To represent this information, the CONTEXT field contains a collection of contextual indices representing information about the speaker, addressee, spatiotemporal location, etc., and a collection of relations such as 'owe-honor' that refer to those indices. (See also Siegel, 2000, and Fukushima, 2002, for related treatments of Japanese honorifics and social role terms.) Paolillo (2000) provides a more elaborated model of registers in Sinhala.

Meanwhile, recent work in variationist sociolinguistics (developing themes introduced in Labov, 1963, and Weinreich *et al.*, 1968) has elaborated the idea that much intra- and inter-speaker variation is the result of speakers creating linguistic (and therefore social) styles out of linguistic alternatives imbued with social meaning (Eckert and McConnell-Ginet, 1992; Eckert, 2000; Irvine and Gal, 2000; Coupland, 2001). 'Social meaning', in this context, is the potential that a particular linguistic form or pattern of linguistic forms has to be used for presenting the speaker's identity, affective state or attitudes, or constructing the speech situation or relationship between the interlocutors as being of a certain type. Linguistic forms bearing social meanings are often integrally involved in the creation (and maintenance) of social

categories, and especially in the elaboration of those categories. For example, gender categories in any given community are elaborated as bundles of properties ('men are strong,' 'women are sensitive,' etc), and linguistic forms are often associated with these sorts of properties (cf. Ochs, 1992).

Why HPSG is Well-Suited to Modeling Variation

Sociolinguistic variation is usually seen as a matter of linguistic performance, but if it is indeed motivated by the social meanings of the variants, it must be supported by a kind of ever-evolving linguistic competence, linking the forms to their social meanings. The question of whether information pertaining to social meanings as well as relative frequencies of occurrence should be part of grammatical competence remains controversial. However, if this kind of information is to be represented within a model of grammatical competence, HPSG is well suited to do so, for several reasons:

As noted above, the social meaning of variant forms can be associated with those forms through lexical or phrasal signs. For example, Paolillo (2000) finds subject-verb agreement only in 'Literary' registers of Sinhala. Paolillo proposes that the linguistic forms associated with the registers in this diglossic situation carry social meanings pertaining to the speaker's attitude toward the message. The agreeing verb forms thus carry a social meaning of 'edited,' whereas the non-agreeing verb forms carry a social meaning of 'interactive.' (These meanings undoubtedly participate in a rich system of categories of social situations and categories of participants in those situations, and take their substance from that interaction.) These attitudes are coded in the formalization as information inside a feature called 'BACKGROUND' within the 'CONTEXT' part of the sign. Thus, all agreeing verbs in Sinhala would have lexical entries including the information shown in Figure 1. These constraints indicate that the verb agrees with its subject, and that it conveys an 'edited' attitude toward the message. (The boxed numbers in this notation indicate identity between the values of two features.)

Nothing in the theory of HPSG precludes there being alternate ways of saying the same thing, that is, there are no cross-derivational constraints putting alternative linguistic forms into direct competition. On the one hand, this means that there are no situations in which one form categorically blocks another. (Note, however, that direct competition can be compatible with surface variation, if the competition is taken to be stochastic; see Anttila, 1997; Reynolds and Nagy, 1994.) This allows HPSG theories of

$$\begin{bmatrix} \text{SYNTAX} & \begin{bmatrix} \text{SUBJECT} & \langle \text{NP} \begin{bmatrix} \text{AGREEMENT} & \boxed{1} \end{bmatrix} \rangle \\ \text{AGREEMENT} & \boxed{1} \end{bmatrix} \\ \text{SEMANTICS} & \boxed{2} \\ \text{CONTEXT} & \begin{bmatrix} \text{SPEAKER} & \boxed{3} \\ \text{BACKGROUND} & \langle \begin{bmatrix} \text{ATTITUDE} & \textit{edited} \\ \text{EVALUATOR} & \boxed{3} \\ \text{MESSAGE} & \boxed{2} \end{bmatrix} \rangle \end{bmatrix} \end{bmatrix}$$

Figure 1 Constraints on agreeing verbs, establishing agreement with the subject and 'edited' attitude (adapted from example (16) of Paolillo, 2000: 245, reprinted with the permission of Cambridge University Press).

sociolinguistic variation to model that variation as arising from a single integrated linguistic competence (or grammar). On the other hand, the lack of cross-derivational constraints leads to a view of variation in which forms do not have to be in competition in order to be socially meaningful. The grammar will include forms associated with different social meanings. Some of these forms will be in competition to the extent that they can be used to express the same propositional content (for example, agreeing and nonagreeing forms of the same verb). Other socially marked forms (e.g., taboo words) may not have unmarked or other-marked alternatives. Thus, sociolinguistic variables narrowly defined as alternate ways of saying the same thing (Lavandera, 1978) are but a special case of socially meaningful linguistic forms.

HPSG takes advantage of type hierarchies in order to capture both fine-grained details of linguistic signs and generalizations at varying degrees of granularity across those signs. The type hierarchy is a multiple inheritance hierarchy, allowing for the statement of cross-cutting generalizations. For example, the type hierarchy for Sinhala might include the information shown in Figure 2. In one dimension are types bearing contextual constraints (e.g., 'this sign conveys the attitude "edited"'). In another dimension are types bearing grammatical constraints (e.g., 'all verbs take subjects'). These dimensions are cross-classified, and particular lexical entries or grammatical constructions would be instances of the cross-classified types. In this way, the theory is designed to 'scale up' so that additional detailed information (such as social meanings or alternative forms) can be added to a grammar without overwhelming or invalidating what is already there. Furthermore, the type hierarchy opens up interesting questions about the nature

Figure 2 Sample multiple inheritance hierarchy illustrating how the constraints allowing a linguistic form to convey a particular attitude can be stated once and inherited by different forms.

of sociolinguistic variables: in this kind of syntactic analysis, some potentially alternating forms are grouped together under a mutual supertype, whereas others may be further separated in the hierarchy. Is social meaning more likely to attach to pairs or sets of variants which are closely related (such as a set of verb forms), or is the syntactic classification of forms irrelevant to their social classification?

Finally, HPSG, a theory of linguistic competence, has been designed to be 'performance plausible,' taking results of psycholinguistic research on processing as motivation for surface-orientation, a constraint-based architecture and strong lexicalism (Sag *et al.*, 2003: Ch. 9). Thus, HPSG as a theory of linguistic competence can be a component of a theory of linguistic performance, including variability. One example of this integration might be found in the modeling of frequency of occurrence via probabilistic information associated with signs. Jurafsky (1996) proposes using a probability-enhanced construction grammar to model psycholinguistic effects in lexical and constructional access and disambiguation (including garden path effects). In a similar fashion, one could associate probability information with sociolinguistic variants to model their frequency of occurrence and the effect of internal (grammatical) constraints on their frequency of occurrence and on their interpretation. This idea is extended in the next section.

Some Proposed Models

Social Meaning and Noncategorical Constraints

Recent work (Bender, 2001; Bender, 2005) has suggested that so-called internal or noncategorical grammatical constraints on particular variants interact with so-called external constraints or the social meaning of linguistic variables. In particular, Bender finds preliminary evidence (through a matched-guise experiment) suggesting that listeners evaluate the same linguistic variant (copula absence or presence in African American Vernacular English (AAVE)) differently depending on the grammatical context. AAVE copula absence has been found across communities to be sensitive to a number of non-categorical grammatical constraints, including the part of speech of the predicate (Rickford, 1998). In Bender's study, AAVE speakers and other African Americans rated copula presence in a disfavoring environment (before an *-ing* form VP) more extremely in response to questions such as 'How well educated does this person sound?' than copula presence in a favoring environment (before an NP).

This effect could be modeled within HPSG by associating a social meaning (e.g., the full richness of what is means to sound 'educated') with the representation of the overt copula, as well as a probability of occurrence which is dependent on the various factors which have been shown to affect its frequency, including the part of speech of its complement. Presumably, speakers choose to use signs when they match a social meaning they wish to convey. The less likely the sign, however, the more strongly a speaker must wish to express that social meaning in order to choose it. Knowing this, listeners will take the sign to be more socially meaningful to the extent that it was unlikely.

Default Speech Act Interpretations of Linguistic Formulae

Terkourafi and Villavicencio (2003) investigate the relationship between interrogative form and a variety of speech acts (requests for action, requests for information, and offers) in Cypriot Greek. They find that in the presence of particular constellations of social information (age, gender, and social class of speaker and addressee, relationship of interlocutors, etc.) certain forms tend to get used to express particular speech acts. They propose to capture this relationship by making use of persistent defaults associated with the forms. For example, in the context of a customer addressing a salesperson, when both are working class, the form *eʃi NP?* ('Are there NP?') is most likely to express an opening request. Terkourafi and Villavicencio propose to encode this by creating a representation for the phrasal sign that includes both the contextual information and the defeasible constraint that the illocutionary force is a request. Because this is a persistent default, it can be overridden if the actual pragmatic information in context indicates otherwise.

Future Directions

Work on sociolinguistic variation in HPSG is only just beginning, and there remain several open questions. One avenue which has yet to be pursued is whether a uniform model of (morpho-)syntactic and phonological variation is possible. If phonological variables can

be associated with social meaning (as they certainly appear to be – cf. Eckert, 2000), can they be analyzed as signs in the HPSG sense? Can these signs be integrated into the same model of grammar outlined here? Do the same kinds of social meanings attach to phonological as well as syntactic variables? How do syntactic and phonological variables interact?

A further, and perhaps more immediate, question pertains to the compositionality of social meanings. In HPSG, the propositional semantics of a sentence is built up compositionally by collecting the semantic contributions of all of the words plus any semantic contributions of the constructions used to put them together. As a starting point, one could hypothesize that social meanings are treated similarly. If different words or constructions contribute contradictory social meanings to the same sentence, these meanings would merely be collected up, and the resolution of their net effect left to an interpretation component. Further research is needed, however, into the nature of such an interpretation component, and whether the combined effect of social meanings attached to linguistic forms is at all dependent on the grammatical relationships between those forms.

Variation and Formal Theories of Syntax, Chomskyan

L Cornips, Royal Netherlands Academy of Arts and Sciences, Amsterdam, The Netherlands

Variable Rule/Linguistic Variable

In the 1960s both sociolinguistic and formal syntax models contained formal rules that could be applied obligatorily or optionally. Formal rules in the earliest Chomskyan transformational model were transformations that connected deep structures with surface structures on the basis of rewrite rules. Optional rules, for example, derived passive, negative, or question sentences from declarative sentences. Labov introduced the concept of variable rule as an extension of this optional rule to include social and stylistic, i.e., external dimensions of language use along with linguistic, i.e., internal dimensions. There is some confusion about the notion of the variable rule since in the earliest literature it refers to both a theoretical model of how to analyze and account for language variation as well as to a method of statistical analysis (Cedergren and Sankoff, 1974). However, both paradigms soon followed their own avenues: the successive transformational models assumed the existence of categorical rules only while variationist sociolinguistics has maintained the notion of the optional rule. The two perspectives on the nature of formal rules reflect deep-seated differences between the two models. The variationist ideas are that the output of a linguistic rule can be probabilistic rather than discrete, and that a linguistic constraint can have a quantitative rather than deterministic effect on the outcome of the process. Formal syntax, however, postulates a blind, deterministic application of a series of procedures given a certain starting point (Chomsky, 1995).

Labov has modified the generative model with the variable rule as a means to accommodate interspeaker and intraspeaker variation. The variationist sociolinguistic practice that has evolved from studies of language variation and change since then takes the principle of accountability as basic (cf, Sankoff, 1990: 296). This principle states that the variants belonging to the same syntactic variable must be specified by the total number of occurrences and the potential occurrences or nonoccurrences in the variable environment, i.e., it ranges between 0% and 100%. It guarantees that the entire range of variability present in the data will be dealt with. The principle of accountability inevitably follows the synonymy principle. This principle is the prerequisite for variants to be assigned to the same linguistic variable: only syntactic variants that are equivocal with regard to referential meaning, i.e., variants that are 'alternate ways of saying "the same" thing,' belong to the same variable. In practice, the assignment of meaning or function of syntactic variants is considered as problematic (Lavandera, 1978).

The indeterminacy of synonymy/functional equivalence is considered not so problematic when examining the phenomenon of verbal agreement, which is present in many vernacular dialects of English all around the world (cf. King, 1994 for French varieties in Canada), as illustrated in (1):

(1a) We parch it (cf. Poplack and Tagliamonte, z1989: 49)

(1b) We parch**es** the coffee

and copula variability, as in African-American Vernacular English (AAVE) (Rickford *et al.*, 1991) or creole varieties, illustrated in (2):

(2a) I **am** just telling the boys (cf. Weldon, 2003:43)

(2b) I'**m** gonna get me a blue tag

(2c) I feel like I Ø fourteen

The examples above illustrate that two or more forms of functional category such as number agreement in (1) and tense in (2) are considered to belong to one linguistic variable. Other linguistic variables that can be found in variationist sociolinguistic practice over the last fifteen years in journals such as *Language Variation and Change* and *Journal of Sociolinguistics* include, for example, null versus overt subjects in varieties of Spanish (Cameron, 1993) and Bislama (Meyerhoff, 2000), particles in Japanese (Takano, 1998) and Mandarin Chinese (Shi, 1989), null versus overt objects in Hungarian (Kontra, 2001), double objects in Dutch (Cornips, 1998), relativization strategies in English varieties and AAVE (Tottie and Rey, 1997), and negation in Scots English (Smith, 2001).

Furthermore, these studies examine nonstandard rather than standard varieties and they may differ considerably in the frequency of the tokens collected, which may range from 29 (Cornips, 1998) to 6809 (Tagliamonte, 1998). It appears that both a low and high frequency of (morpho)syntactic variables may reveal significant correlations between the use of linguistic variants and social dimensions in the speech community.

Structural Representation of the Syntactic Variants

In addition to the synonymy principle, the notion of the linguistic variable as a structural unit was also based on the assumption that the variants have an identical underlying structure or representation, which is subject to variable surface realizations (Winford, 1996: 177). So the alternation between active and passive examples was considered to be instances of different surface manifestations of the same underlying or deep structure. Santorini (1993) and Pintzuk (1995) are examples of studies within the government and binding framework where it was argued that different word orders such as SOV and VSO are derived by movement. However, in later generative models, the idea of a derivational model was abandoned in favor of a configurational model (most recently Minimalism), in which a single representation is subject to various constraints. An example is the study of Meechan and Foley (1994), where variable verbal number agreement in existentials was analyzed as a reflection of different configurational positions of the postverbal NP (a second example is Meyerhoff, 2000).

As a consequence, the original notion of the linguistic variable as a structural unit such that syntactic variants are different surface realizations of an underlying structure has been lost too. The consequences are that the syntactic variable as a structural unit has to be defined again depending on the particular model of syntax one employs. Other studies that can be mentioned in the older principles and parameters framework are Henry (1995) and Cornips (1998), where variants constituting the linguistic variable were brought about by different properties of functional categories. Since the consecutive models in generative grammar follow each other at rather high speed, different makeups of the structural unit can be detected in recent decades.

An Overall Theory of Grammar and the Locus of Variability

Many researchers claim that a bridge between variation and theory remains possible; that is, it is assumed that there exists a fairly direct connection between grammar and language usage. The organization of the grammar may be reflected in the patterns of usage (Taylor, 1994) or quantitative results may lend strong support to structural analysis (Pintzuk, 1995). Or, to put it differently, through the use of variationist methodology and knowledge about the factors contributing to syntactic variation, one catches "a glimpse of grammatical structure" (Meechan and Foley, 1994: 82). Wilson and Henry (1998: 8) phrased the advantages of an overall theory of grammar including variation and formal theory as follows: "We may be able better to understand language variation and change as they are driven by social factors but constrained (at one level) by the nature of possible grammars." One problematic issue in this socially realistic account is how to account for the fact that individual speakers can use several variants of the syntactic variable when maintaining the same style level. This issue is related to the questions within the successive generative models about the locus of syntactic variation, and its restrictions and predictions. In the literature, two alternative approaches to this 'choice' have been suggested (Muysken, 2005). Either the 'choice' is put outside the grammatical mechanisms (Kroch, 1989; Adger and Smith, 2005), or it is put inside the grammar by re-introducing optional rules (Wilson and Henry, 1998; Henry, 2002). The first option was advocated by Kroch and his associates, who claimed that grammar is a blind, autonomous system and the notion of 'choice' (optionality, variability) is not part of it. Instead, the individual speaker revealing variability has separate or competing grammars. Adger and Smith (2005) also argued that the notion of 'choice' cannot be accounted for within the autonomous grammar. In contrast with Kroch's vision, this does not imply that individual speakers "have different grammars, *per se*, but rather a range of lexical items open to them, some of which will have syntactic effects." In their analysis, the notion of 'choice' concerned the level that serves as the input for the autonomous grammatical system. However, Henry (1995) argued that individual grammars include variability and, consequently, the speaker has a real choice in terms of syntactic operations, for instance, optional verb movement. However, all agreed that an analysis of language use (quantitative analysis, intra- and interspeaker variation) in addition to formal theory, i.e., the study of both internal and external constraints, has the potential not only to assess but also to refine theoretical conceptions of linguistic structure.

Variation and Language: Overview

The Locus of Variation

If structure is at the heart of language, then variation defines its soul. As Sapir (1921: 147) put it, "Everyone knows that language is variable." Furthermore, variation allows us to differentiate individuals, groups, communities, states, and nations. Notwithstanding the pervasive nature of variability in language, it often has been disregarded or dismissed as tangential to the description of structural patterning and irrelevant to the study of linguistic competence. In fact, it was not until the advent of sociolinguistics a half century ago that the admission of language variation became more than a footnote to linguistic description. The study of language variation is now one of the most rapidly expanding subfields of linguistics with a well-established cohort of researchers, regular conferences, and scholarly journals, but its status is still somewhat marginal within theoretical linguistics, notwithstanding the insistence of William Labov that the study of language variation is central to the solution of fundamental problems in linguistic theory (e.g., Labov, 1966, 2001).

Variability is everywhere in language, from the unique details in each production of a sound or sign to the auditory or visual processing of the linguistic signal. In fact, one of the amazing facts about human communication is the demonstrated ability to normalize the inherent variation within every spoken or signed message in processing the linguistic signal. Although language variation is persistent and pervasive, it is not all equally interesting, even to those who focus on the systematic nature of language variation, so-called language variationists. For example, there is considerable variation in speech or sign production related to the physical make-up of an individual speaker or signer – differences in vocal tract size in spoken language or differences in the size of the hands and body used in signing – that is of interest to those who study language normalization, but this is not generally the focus of systematic language variation studies. Similarly, the relative fluency of production related to idiosyncratic behavior is not of concern to those interested in language variation, although the dichotomy between meaningful social differences and socially insignificant personal differences is not always clear-cut. Generally speaking, interest in language variation focuses on differences that have some social significance in terms of group behavior rather than personal idiosyncrasies, although socially meaningful aspects of individual speaker performance are of interest to those interested in language variation.

The empirical reality is that the boundaries of significant and insignificant language variation are often gradient and obscure rather than discrete and transparent. There is, for example, a fine line between consequential and inconsequential fluctuation in the vowel formants of repeated productions of a given vowel in a constant phonetic context. Some variability in each vowel production is expected, but a larger envelope of fluctuation in the formants might be indicative of a significant vowel change in progress. Determining significance for an envelope of vowel formants, however, can only be arrived at through a series of exploratory procedures that takes into account individual speaker traits, social group norms, the production of other vowels in the system, and so forth. Obviously, the empirical boundaries of investigation for language variation studies are not as straightforward as they may appear in descriptions of systematic variability found in the research literature and often involve preliminary decisions about what to include and what to exclude in the study of orderly variation.

In traditional linguistic description the notion of variation within structural units has often been acknowledged under labels such as 'free fluctuation,' 'optional rules,' and 'free variants.' Although long recognized, this variability has nonetheless been considered to be "an area of little importance" (Crystal, 2003: 189), a kind of garbage heap for variants that could not be predicted invariably within the categorical framework assumed under most models of linguistic description. But in keeping with the adage that "one person's garbage is another person's treasure," the examination of such variation has become the cornerstone of sociolinguistics, with several professional journals dealing regularly with issues of language variation, including one dedicated exclusively to this issue (*Language Variation and Change*), and prominent sociolinguistics conferences that routinely feature presentations on language variation. This includes perhaps the most influential sociolinguistics conference in the world, the annual conference New Ways of Analyzing Variation (NWAV), now well into its third decade of continuous growth.

The Linguistic Variable

An essential construct in the study of linguistic variation is the linguistic variable, a structural unit that includes a set of fluctuating variants showing meaningful co-variation with an independent set of variables.

The linguistic variable was explicitly set forth in early variation studies by William Labov (1966), the acknowledged founder of the field of language variation studies, although this construct was certainly implicit in work previous to that point. On one level, the relationship of the variable to its variants may be likened to that of the classic emic-etic relationship in linguistic description, such as that between a morpheme and its allomorphs or a phoneme and its allophones; however, as we shall see, it is hardly confined by such structural relationships and boundaries. The unit is an abstraction because linguistic variables have no concrete reality apart from the particular variants through which they are realized.

Operationally, the linguistic variable has been used to encompass a wide range of fluctuating variants. The set may be a structural type, such as grammatical category (e.g., a tense category, possessive category), a phoneme (e.g., the phoneme /θ/ or the phoneme /ŋ/ in English), or a natural class of items in a specific linguistic context (e.g., coronal stops in syllable-coda position). It also may be defined in terms of the application of a general process, such as the use of a particular type of contraction (e.g., English variation between *She has not* vs. *She hasn't* vs. *She's not*) or in terms of a syntactic relationship, such as concord (e.g., negative concord in English as in *He didn't do anything about any problem* vs. *He didn't do nothing about no problem*) or phrasal constituency (e.g., head-initial vs. head-final phrases). Variants are usually established apart from theoretical models of language description and may, for all intents and purposes, be accommodated within any syntactic model (e.g., Principles and Parameters, Minimalism, Head-Driven Phrase Structure Grammar, Lexical Functional Grammar, and Construction Grammar) or phonological model (e.g., Generative Phonology, Lexical Phonology, Optimality Theory, Exemplar Theory), although there are significant implications for how such variation may be accommodated within a particular model of language. Finally, the linguistic variable may be defined as a simple lexical choice (e.g. *soda*, *pop*, *tonic*, or *co(ca)-cola* for a carbonated drink in various regions of the United States) or even in terms of a speech act (e.g. alternatives for a expressing a 'directive' or a 'compliment').

As noted, the linguistic variable can cover a full range of linguistic units and relationships. By the same token, the relationship of the variants to each other is not necessarily limited by the fundamental typology operative in linguistic analysis and description. For example, a given phonological variable may encompass allophonic fluctuation within a given phoneme, different phonemes, or combine allophonic and phonemically distinct variants within a unitary variable. Thus, the pronunciation of the vowel of English words like *coffee* or *caught* may involve variants that range from different phonetic productions within the same phonemic vowel (e.g., [kaofi] vs. [koəfi]) to a phonemic merger with another phonemic unit (e.g., the vowel of *caught* and *cot* are both pronounced as [*a*]). In this case, the variants appear to be united by the fact that they exist within a single lexical item. Furthermore, in some applications of the linguistic variable, variants may involve competing systems or grammars (Kroch, 1989) so that variation cannot even be considered inherent within a unitary system. Under this interpretation, typological correspondence or equivalency in the competing systems is the apparent basis for including different variants in a linguistic variable.

The notion of the linguistic variable has been applied to a full range of levels within language, although not without some argument about its appropriate application. Phonological and morphosyntactic variation have tended to dominate language variation research in synchronic and apparent time studies while syntactic variation has been a significant locus of investigation in diachronic studies. For synchronic and apparent time studies, which have tended to use natural conversational interviews as their primary databases, there is both a practical and theoretical explanation for the focus on phonology and morphosyntax. In natural conversation, syntactic phenomena simply do not occur at sufficient frequency levels for meaningful quantitative analyses of systematic variability, the procedural underpinning for variation studies. But there also have been theoretical concerns about the application of variation studies beyond phonology related to the assumption of 'semantic equivalency,' that is, the notion that there is no change in referential meaning based on the selection of one variant or another (Lavandera, 1978). Although it may safely be assumed that the variant pronunciations of unstressed *–ing* in the English word *running* as a final velar [ŋ] or coronal nasal [n] have the same denotational referent, questions about semantic equivalency have arisen in examining variation on other levels. For example, it may be argued that there are subtle meaning differences in the Montreal French use of variants *être* and *avoir* in different contexts (Sankoff and Thibault, 1977). Similarly, it may be questioned whether the difference between the 'active,' '*be* passive,' and '*get* passive' in English (e.g., *They broke into the store* vs. *The store was broken into* vs. *The store got broken into*) are authentic alternatives for "saying the same thing" (Weiner and Labov, 1983). Lavandera (1978) has suggested that the condition of strict semantic equivalency need not be applied rigorously so that the linguistic

variable could be used in study language variation beyond phonology, a guideline now generally adopted in studies of syntactic variables.

The focus on syntax in diachronic studies of language variation is, to a large extent, a product of the kinds of available texts for investigation. Historical documents tend to be more reliable for examining grammatical than phonetic and phonological variation. Furthermore, the increasing accessibility of mega-corpora with automated search capabilities for historical texts has made the investigation of syntactic variability much more accessible to variation researchers.

Although there are lingering questions about the precise structural status of the linguistic variable, it remains a primitive construct in the study of language variation. Most of the lingering questions and qualifications have to do with its precise status as a structural unit and its possible relationship to a grammar of language rather than its usefulness as convenient heuristic in the investigation of language variation. Whether or not it is explicitly recognized, the linguistic variable remains at the procedural foundation of variation analysis, because one must assume that the analyst can delimit a unified, exclusive set of fluctuating language variants that shows meaningful patterns of co-variation with an independent set of variables. Although sensitive to traditional structural categories and relationships in language, the linguistic variable is not necessarily beholden to them, and there are clearly cases where the imposition of a traditional linguistic boundary may actually detract from rather than enhance the understanding of language variation in its social context (Wolfram, 1993). Such considerations may be one of the reasons why it might be argued that the linguistic variable is a uniquely sociolinguistic construct that conveniently – if not always comfortably – covers the locus of co-variation between linguistic variants and other variables that include social, historical, psychological, and linguistic factors.

Systematic Variability

As noted, the significance of the linguistic variable lies in its co-variation with other factors, or independent variables. These factors do not typically correlate with the categorical use of a variant but with the relative frequency of variant occurrence. For example, in most varieties of English, there is fluctuation in the production of the final segment of words such as *swimming* and *walking* with a coronal nasal [n] vs. a velar nasal [ŋ], commonly represented in spelling as *–in'* vs. *–ing*, respectively. Studies of the fluctuation between these variants over a half century now (e.g., Fischer, 1958; Shuy, Wolfram, and Riley, 1967; Kiesling, 1996) have shown that the relative frequency of the *-in'* variant correlates with various types of social, psychological, and linguistic factors. For example, Fischer (1958) showed that boys tended to use more *-in'* than girls and that differences also related to speaker personality type (aggressive vs. cooperative) and mood (tense vs. relaxed); Shuy *et al.* (1967) showed that *–in'* was more frequently used by lower status groups than higher status ones, and Kiesling (1996) showed that a group of fraternity men used *-in'* more frequently to project different types of masculine images during fraternity meetings associated with relations of power and solidarity. At the same time, studies have shown that there is variation in the use of the *–in'* variation based on the lexical category of the word, as verbs are more likely to occur with *in'* than nouns (Fischer, 1958). In all of these cases, the difference in *-in'* usage is a matter of relative frequency rather than categorical predictability – a tendency in which variants have a greater or lesser likelihood of occurring under certain conditions.

Factors that correlate with higher and lower frequency levels of a given variant are referred to as constraints on variability, in which the term 'constraint' is used to refer to a factor that systematically correlates with increased likelihood that a given variant will occur. This use is somewhat different from how the term is used in theoretical linguistics, where constraint is used to refer to a condition that characterizes a universal principle of language or a condition that restricts a language-specific rule. Factors that correlate with the increased frequency of a variant are said to favor the occurrence of a variant, whereas those that correlate with reduced frequency disfavor or inhibit the occurrence of the variant.

Independent variables that co-vary with systematic differences in the relative frequency of a variant are of two primary types, structural linguistic factors related to the linguistic system itself, so-called internal constraints, and social or sociopsychological factors of various types that exist apart from the linguistic system, so-called external constraints. Independent linguistic constraints seem to align closely with traditional types of structural units considered relevant in linguistic description. Thus, for systematic phonological variation, the feature composition of the variant (e.g., voicing, sonorancy), phonetic environment (e.g., preceding and following segments, stress patterns), hierarchical status (e.g., syllable position), and grammatical status (e.g., type of morpheme) may be factors that constrain variability. There also may be other factors, such as the lexical condition that high-frequency words favor a variable process over low-frequency words (Myers and Guy, 1997). For

morphological and syntactic variables, lexical category (e.g., noun vs. verb), phrasal composition (e.g., NP vs. VP, heavy vs. light phrases), co-occurrence relations (e.g., concord, phrasal complements), embedding (matrix vs. embedded clause), and adjacency conditions (proximate vs. distal) may be relevant factors affecting the relative usage of fluctuating variants. These are, of course, the kinds of factors considered in traditional qualitative syntactic descriptions. As with phonological variables, this typology may be extended somewhat, so that factors such as the serialization of structures in a narrative sequence, for example, may affect variability along with the reified, sentence-level grammatical categories and constituents generally recognized in syntactic description.

The types of external variables that correlate with the relative frequency of fluctuating variants may include traditional demographic variables (e.g., age, social class, region), constructed social groupings and practices of various types (e.g., communities of practice, social networks), interactional dynamics (e.g., power relations, solidarity), and even personal presentation styles and registers (e.g., performance, mimicking). Although there seems to be somewhat of a disjunction between systemically based linguistic factors and a broadly ranging array of social and psychological factors, most studies of systematic variation include both independent linguistic and social factors within the same description of linguistic variability. Furthermore, one of the principles that has guided variation analysis over the past few decades is the "principle of multiple causes" (Bailey, 2002: 118), which holds that no single contextual factor can satisfactorily describe the variability observed in natural language. Thus, linguistic factors such as structural composition and linguistic environment may combine with a set of social factors such as age, status, situational context, and so forth in the description of systematic variability.

Although an assortment of linguistic and social variables need to be considered in accounting for systematic variability, not all are of equal magnitude in their orderly effect on the occurrence of variants. To sort out the relative influence of different constraints on variability, variationists often use a type of multivariate regression analysis model designed by the mathematician and linguist, David Sankoff, known as VARBRUL (Cedergren and Sankoff, 1974). Although a variety of commercially available multivariate regression analyses might be applied to determine the significance of various factors on the co-variation of linguistics variants, VARBRUL was designed specifically to handle the kinds of data found in language variation, where not all of the logical cross-products may be manifested and there is often quite unequal distribution of tokens in different cross-product cells in the sample.

Table 1 Illustration of results of VARBRUL analysis (from Mallinson and Wolfram, 2002)

VARBRUL Results
Input probability = .29
Ethnicity
African Americans = .65; European Americans = .33
Grammatical Status
Monomorphemic = .56; bimorphemic = .39
Following Environment
consonant = .80; pause = .37; vowel = .24
Total Chi square = 3.085 Chi square per cell = .257

VARBRUL is a probabilistic-based statistical procedure that shows the relative contributions of various factor groups to the overall variability of items. The weighting values range from 0 to 1 so that a value of greater than 0.5 in a binomial application indicates that the factor being considered has a favoring effect on the occurrence of the variant, whereas a value of less than 0.5 indicates a disfavoring effect; in a trinomial application, a value of more than 0.33 would indicate a favoring effect and a value less than 0.33 would be a disfavoring effect. The higher the VARBRUL weighting is, the stronger the effect of the factor is in accounting for the variability. Both Microsoft and MacIntosh versions of this program are readily available and commonly used by researchers in language variation studies. In Table 1, taken from Mallinson and Wolfram (2002), results from a VARBRUL analysis of the incidence of syllable-coda, stop-final cluster reduction in a remote Appalachian region of North Carolina (USA) are presented, following a conventional procedure for reporting such data. In this binomial analysis based on the application or nonapplication of cluster reduction, the input probability represents the overall application mean of cluster reduction apart from the constraining effects. Two independent linguistic variables, or factor groups, are considered in this simplified presentation, the morphemic status of the cluster (e.g. monomophemic as in *guest* or *mist* vs. bimorphemic as in *guessed* or *missed*) and the following phonetic environment (e.g. consonant as in *guest parking*, vowel as in *guest appearance*, and pause as in *guest* //), and one social factor, ethnic group membership (European American vs. African American). The total Chi square and the Chi square score per cell (i.e., preconsonantal, monomophemic, African American/prevocalic, bimorphemic, European American/etc.) indicate the goodness of fit for the quantitative data.

The data indicate that a following consonant (.84) strongly favors cluster reduction over a following pause (.37) and vowel (.24), and that cluster reduction is favored for monomorphemic (.56) over bimorphemic (.39) clusters. Alhough both following phonetic environment and morphemic status are significant constraints on variability in this study, the following phonetic environment is a stronger constraint than the morphemic status of the cluster. The analysis also reveals that ethnic group membership is a strong social effect on variability, with African Americans (.65) favoring cluster reduction over European Americans (.35).

Although VARBRUL has become the regular statistical program for determining the systematic effect of various constraints on variability, it is not without limitations. Some of these are a product of the procedural assumptions, but some arise from deeper questions about the nature of variation itself. For example, one of the assumptions of VARBRUL is the independence of factor groups, for example, the assumption that the effect of following phonetic environment operates independently from the morphemic status of the cluster. As Sigley (2003) points out, however, both linguistic and social factors are often interactive. With respect to social factors, for example, ethnic group membership may work in tandem with the social factors of age and social class rather than operate independently; similarly, for linguistic factors a suprasegmental effect such as stress may interact with a segmental effect related to the following or preceding phonetic environment. The assumption of independence in effects is therefore questionable, leading to the development of more refined statistical procedures to tease out these interaction effects (Sigley, 2003). There also are lingering questions about how such linguistic and social constraints might be represented in a grammar that includes systematic variability.

Another issue raised by procedures such as VARBRUL relates to group and individual variation. VABRUL analyses are typically based on aggregate data, that is, pooled data for a designated group of speakers without reference to an individual speaker. This procedure obscures variation patterns for individuals, raising the issue of whether or not we can assume that the individual and the group are the same with respect to systematic variation – a kind of homogeneity assumption. Empirical investigations of individual speakers in relation to group norms show that there is impressive regularity from speaker to speaker with respect to the constraint effects on variation, once a reasonable number of tokens are extracted from individual speakers. This leads Guy (1980: 12) to conclude that group norms "recapitulate the generally uniform norms of individuals." Some of the replicability of constraint effects for individual speakers may, however, be due to systemic principles inherent within language itself. It makes phonetic sense, for example, that syllable-coda cluster reduction would be much more likely take place when the following segment is a consonant as opposed to a vowel, given the phonetic complexity of consonant sequencing without intervening vowels. Other constraints, however, seem language specific, such as the relationship between a following pause and following vowel in their effect on variability (Labov, 1994). Although there is sometimes an impressive replicability in terms of constraint effects from speaker to speaker, there may be considerable variation in the overall levels of variation for individual speakers, and some differences in relationships between constraint effects for individual speakers within a group.

Detailed studies of groups and individuals show that one cannot assume that they are always the same with respect to variation, and that there may be considerable variability among speakers within a relatively homogeneous social group. In fact, Dorian (1994) suggests that there is a kind of "personal-pattern variation" that does not co-vary with external social factors. Speakers are both individuals with idiosyncratic life histories as well as affiliated members of a complex array of social groups, making it impossible to explain away all individual-based variation in terms of group norms.

Variation and Language Change

One of the most fruitful areas for the application of language variation analysis is language change, given the fact that change necessarily involves variation. Speakers do not go to bed one night using a particular form only to wake up the next morning to find the form categorically replaced by another one. Variation exists whether the change involves a gradual, imperceptible shift in the phonetic value of a vowel within a continuum of phonetic space or is an abrupt, readily transparent change involving a major syntactic realignment of phrasal constituents. In the progression of language change, there is a transitional period of co-variation between old and new variants. Although all change seems to involve variation, this does not mean that all variation necessarily implies change. Some variation may be stable, a product of internal systemic and natural performance phenomena rather a reflection of dynamic directionality. Sorting out dynamic and stable variation is, however, not always obvious, and can not necessarily be determined *a priori*. In most cases, decisions about transitional and stable variation can be made only after examining

Table 2 Variation model of change following Bailey (1973)

Stage of change	*E_1*	*E_2*
Categorical status, before undergoing change	A	A
Early stage, begins variability in restricted environment	A/B	A
Change in full progress, greater use of new variant in E1 where change first initiated	A/B	A/B
Change progresses towards completion with categorically of new variant first in E1 where change initiated	B	A/B
Completed change, new variant categorical	B	B

Figure 1 Model of *S* curve in language change.

patterns of variation across time and by considering underlying psycholinguistic and sociolinguistic principles that might help determine the difference.

Although the variability inherent in change has sometimes been ignored in historical linguistics under the traditional assumption that language change could not be directly observed, the empirical analysis of language change at different points in real time and in 'apparent time' (i.e., the assumption that differences across different generations of speakers at a given point in time will mirror actual diachronic change) indicates that the variable transition of variants proceeds in an orderly fashion over time and space.

Various models have been proposed for capturing the systematic heterogeneity associated with change. One of the earlier models (Bailey, 1973) proposed that change started variably in a limited, natural linguistic environment and then spread from that point to other environments. Furthermore, this model assumed that that variable change in the earliest environment would ideally show greater variability than changes in other environments where the change started later, so that relationships of 'more' and 'less' with respect to new forms might reflect chronological relations of 'earlier' and 'later.' This relationship can be illustrated by setting up a simplified, ideal model of the stages of change as in Table 2, following Bailey (1973). The table models the progression from the categorical use of one form, A, to another, B, in two different linguistic environments, E_1 and E_2.

The model in Table 2 illustrates the 'sequential actuation' of change (Pintzuk, 2003: 513), in which a change starts in one linguistic environment, a more favored environment, and then spreads to a less favored one. However, speakers also may initiate a new form at the same time in different environments, so-called 'simultaneous actuation,' or initiate change at different frequency levels in different environments. Cases of simultaneous change, along with other factors that may accelerate or impede a change over time, call into question the assumption that 'more' and 'less' can be interpreted without qualification as 'earlier' and 'later.'

The progression of variable change over time has now been subjected to considerable scrutiny in historical linguistics, particularly with reference to syntactic change (e.g., Kroch, 1989; Kroch and Taylor, 2000; Pintzuk, 2003). Although it was originally suggested (Bailey, 1973) that more favorable contexts for change might progress at an accelerated rate by comparison with less favorable contexts, research by Kroch and his colleagues supports the conclusion that there is a Constant Rate Effect (CRE) in change, in which the rate of change for each context is the same even though the frequency of competing forms may vary across linguistic contexts. It is important to understand that the label 'constant' does not refer to a constant rate of increase in frequency over time but to the fact that change will be the same across different linguistic environments, so that the progression of change in E_1, E_2, and E_n will follow the same trajectory slope.

The study of language change also indicates that there is a prototypical progression slope for variation in time, where change typically follows that of an S-shaped curve (Bailey, 1973; Labov, 1994; Pintzuk, 2003). That is, the replacement of form A with B occurs slowly at the beginning of a change, accelerates rapidly during the mid-course, and then tails off slowly in the final stages of the change, as illustrated in Figure 1.

This model has implications on several different levels. For example, the relatively rapid rate of progression through the mid-course of change sometimes makes this period less accessible to direct observation than the slower periods at the beginning and end points. It also may have implications for the regularity of a change. For example, the role of lexical conditioning in phonological change may be more prominent at the incipient and cessation stages of the

change, with lexical diffusion playing a more prominent role at the endpoints. Furthermore, irregularity in constraint effects on variability may be more prone to take place at the beginning and end points of the change than they might be during the mid-course of a change.

The examination of systematic language variation over time offers a unique opportunity to observe language change in progress. More important, it has moved historical linguistics away from a long-held belief that diachronic linguistics was limited to post-hoc analysis of the end-products of language change (Weinreich *et al.,* 1968). Indeed, language change has proven to be one of the most productive venues for studying the nature of systematic variability as well as providing an important proving ground for examining the empirical validity of different models of language change.

Variation and Language Knowledge

As a methodological heuristic, there is little question about the usefulness of variation analysis. Its implications for the representation of speakers' language capabilities and the role of variation in a language grammar, however, is much more disputable. In fact, most theoretical linguists would simply dismiss systematic variability as an artifact of performance with little relevance for a model of language competence. Notwithstanding a few exceptions (e.g., Guy, 2003; Anttila, 2003), far too little attention has been paid to the role of systematic variability in a grammar of language.

Although the question of speaker knowledge and language variation has been raised on occasion (Cedergren and Sankoff, 1974), surprisingly little discussion has focused on the capabilities that speakers might have with respect to language variation as a putative attribute of language competence. Possible claims about speaker capabilities may include the following, ranging from the weakest to the strongest claim.

- Speakers can identity optional (variable) variants
- Speakers can identify the factors that favor and inhibit variable application
- Speakers can identify the relative strength of different constraints on variable application
- Speakers can identify a probabilistic mechanism that generates differential constraint effects
- Speakers can identify frequency levels of variation.

There is little psycholinguistic experimentation to support any of these claims, although there is evidentiary documentation that the speaker-hearer can at least recognize optional variants and distinctions between groups and individual speakers based on relative frequency levels. Insight into the finer details of speaker knowledge, such as evidence for knowledge about the relative strength of constraints, the recognition of a probabilistic mechanism for generating constraint effects, and knowledge of frequency levels, however, still awaits psycholinguistic experimentation.

In the early days of variation studies, researchers (Labov, 1969; Cedergren and Sankoff, 1974) proposed that variation was inherent within a language system and part of speaker competence, and hence should be integrated into the grammar. This was expressed formally in so-called variable rules, which incorporated ordered constraint effects, and even probabilities, into the formal generative-style rewrite rules in the tradition of Chomsky and Halle (1968). As formal grammars shifted toward the formulation of universal principles rather than specific language rules, however, the variable rule was abandoned (Fasold, 1991). At the same time, reformulated models of grammar raised new issues about the assumed inherency of variation that was once considered to be the cornerstone of variation theory. In the Principles and Parameters model of syntax, for example, it is assumed that parameters are set for a given language in one way or another, whereas in Optimality Theory in phonology variability is reduced to different rankings among the universal constraints on phonological structure. Accordingly, variation consists of alternative settings of the parameters or rankings and speakers have at least two grammars, one set in one way and one set in another. As Fasold (2003: 232) puts it, "Variation in this tradition is not distinguished from bilingualism; such speakers have two more nearly identical grammars and can produce utterances reflecting either or any of them." Thus, in current studies of variation in historical syntax, variation is now interpreted as grammatical competition between two distinct options that do not ordinarily allow optionality – for example, head-initial versus head-final phrasal structure (Pintzuk, 2003) – so that options correspond to contradictory settings of the parameters.

Although it may be possible to view some kinds of syntactic variation as competition between different grammars of language rather than inherent variability, this interpretation is less comfortably applied across different levels of language. For example, the phonetic realization of vowels may naturally exist on a continuum in phonetic space. Furthermore, given the range of variation in phonology and phonetics, there is an exponential proliferation of possible grammars – into the hundreds and thousands – that seems counterintuitive. The interpretation of variation as a product of competing grammars must also

be reconciled with the intuitions of speakers themselves, who may, for example, view variants to exist within a unitary system. Although attempts have been made to reconcile the systematic nature of variability and alternative rankings in Optimality Theory (Guy, 2003; Anttila, 2003), the mechanisms for incorporating such variability into the grammar still seem somewhat ad hoc, and Guy observes that Optimality Theory seems unable to capture the stability of constraints in the variationist model (Guy, 2003: 383).

The potential role of variation in a formal grammar of language remains one of the most challenging – and intriguing – prospects for those who have empirically demonstrated the validity and reliability of systematic variation in language. The systematic nature of structured heterogeneity seems to be indisputable, but its role within a model of language claiming to represent speaker capabilities persists as an issue for variationists and formal theoreticians to contemplate, preferably together.

Variation in Arabic Languages

E Al-Wer, University of Essex, Wivenhoe Park, UK

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Arabic is a native language to some 200 million people, distributed over 22 different countries collectively known as the 'Arab World.' The Arab World stretches from the Indian Ocean in the east to the Atlantic Ocean in the west and includes most of the countries of the Middle East, the whole of North Africa, and Sudan (as well as Somalia and Mauritania). The Asian part of the Arab World is commonly referred to as al Mashreq 'the East,' and the North African part (particularly from and including Libya westwards) as al Maghreb 'the West.' Egypt represents the geographical link between the East and the West, and the Egyptian dialects may be thought of as a bridge between the Maghreb and the Mashreq dialects. In terms of demographic distribution, approximately 66% of the total population live in the African part. The largest concentration of Arabic speakers is in Egypt (67 million).

A Historical Sketch

The ancient home of the Arabs is the Arab Peninsula, and the Arabic language is traced to the second millennium B.C. in the northern part of the peninsula. To varying extents, everywhere else, Arabic is a relative newcomer. From the peninsula, and starting in the second half of the seventh century A.D., the language was disseminated first through direct military conquest, and later it affirmed its position through intellectual influence. In the course of its spread northwards to the eastern Mediterranean, Mesopotamia, and Egypt it ousted Greek, Persian, Aramaic, and Coptic. In the Maghreb, Arabic obscured Berber, and although it never managed to obliterate Berber, which continues to be spoken by no less than 40 million people, it altered the linguistic shape of the region.

Arabic prospered in a climate of dominant Arab civilization and declined alongside the diminution in power and influence of the Arabs. The rise to power of the Ottoman Turkish Empire in the 16th century resulted in the replacement of Arabic by Turkish as the language of state administration, although Turkish never managed to replace colloquial Arabic as the everyday language of communication in the Arabic speaking provinces. The Ottomans lost the Maghreb in the mid-19th century (to Italy in Libya, and to France in Morocco, Algeria, and Tunisia), and Egypt to Napoleon for a short period of time and then to Britain. The outcome of the First World War brought an end to Ottoman rule in the Mashreq. Most of the Arabic speaking provinces were then divided into separate political entities and were placed under the tutelage of Britain and France. The linguistic significance of these developments was mainly that French and English became important features on the linguistic scene. English, however, did not influence the linguistic identity of the regions that came under British rule; it became at best the most widely spoken foreign language. French, on the other hand, had a far-reaching influence that continues to be visible, especially in the Maghreb, to this day. Much of the colonized or mandated territories became independent by the early 1960s, and Arabic has since then been declared the official language in Arab World.

Varieties of Arabic

To provide a concise outline of variation in Arabic, I will deal with two issues: the linguistic resources available to speakers of Arabic, and the sociolinguistic determinants of variation in Arab communities.

Standard Arabic

Throughout the Arab World, Standard Arabic (a modernized version of Classical Arabic), in an almost invariant form, is designated as the official language, the medium of instruction in education, and the language of the mass media, although in actual practice a mixture of Standard and colloquial varieties is used in education and in the media. The language was standardized twelve centuries ago, and the Standard variety has not been a spoken language for longer than that (see Holes, 1995a). It is not ordinarily used for everyday spoken purposes by any sector of the population. A functional knowledge of it is attainable through formal learning only, i.e., it is not acquired

Introduction

Arabic is a native language to some 200 million people, distributed over 22 different countries collectively known as the 'Arab World.' The Arab World stretches from the Indian Ocean in the east to the Atlantic Ocean in the west and includes most of the countries of the Middle East, the whole of North Africa, and Sudan (as well as Somalia and Mauritania). The Asian part of the Arab World is commonly referred to as al Mashreq 'the East,' and the North African part (particularly from and including Libya westwards) as al Maghreb 'the West.' Egypt represents the geographical link between the East and the West, and the Egyptian dialects may be thought of as a bridge between the Maghreb and the Mashreq dialects. In terms of demographic distribution, approximately 66% of the total population live in the African part. The largest concentration of Arabic speakers is in Egypt (67 million).

A Historical Sketch

The ancient home of the Arabs is the Arab Peninsula, and the Arabic language is traced to the second millennium B.C. in the northern part of the peninsula. To varying extents, everywhere else, Arabic is a relative newcomer. From the peninsula, and starting in the second half of the seventh century A.D., the language was disseminated first through direct military conquest, and later it affirmed its position through intellectual influence. In the course of its spread northwards to the eastern Mediterranean, Mesopotamia, and Egypt it ousted Greek, Persian, Aramaic, and Coptic. In the Maghreb, Arabic obscured Berber, and although it never managed to obliterate Berber, which continues to be spoken by no less than 40 million people, it altered the linguistic shape of the region.

Arabic prospered in a climate of dominant Arab civilization and declined alongside the diminution in power and influence of the Arabs. The rise to power of the Ottoman Turkish Empire in the 16th century resulted in the replacement of Arabic by Turkish as the language of state administration, although Turkish never managed to replace colloquial Arabic as the everyday language of communication in the Arabic speaking provinces. The Ottomans lost the Maghreb in the mid-19th century (to Italy in Libya, and to France in Morocco, Algeria, and Tunisia), and Egypt to Napoleon for a short period of time and then to Britain. The outcome of the First World War brought an end to Ottoman rule in the Mashreq. Most of the Arabic speaking provinces were then divided into separate political entities and were placed under the tutelage of Britain and France. The linguistic significance of these developments was mainly that French and English became important features on the linguistic scene. English, however, did not influence the linguistic identity of the regions that came under British rule; it became at best the most widely spoken foreign language. French, on the other hand, had a far-reaching influence that continues to be visible, especially in the Maghreb, to this day. Much of the colonized or mandated territories became independent by the early 1960s, and Arabic has since then been declared the official language in Arab World.

Varieties of Arabic

To provide a concise outline of variation in Arabic, I will deal with two issues: the linguistic resources available to speakers of Arabic, and the sociolinguistic determinants of variation in Arab communities.

Standard Arabic

Throughout the Arab World, Standard Arabic (a modernized version of Classical Arabic), in an almost invariant form, is designated as the official language, the medium of instruction in education, and the language of the mass media, although in actual practice a mixture of Standard and colloquial varieties is used in education and in the media. The language was standardized twelve centuries ago, and the Standard variety has not been a spoken language for longer than that (see Holes, 1995a). It is not ordinarily used for everyday spoken purposes by any sector of the population. A functional knowledge of it is attainable through formal learning only, i.e., it is not acquired

naturally. It stands in a diglossic relation to the spoken dialects (e.g., Spoken Egyptian Arabic), very much along the lines explained by Ferguson (1959).

The fact that this variety is not associated with a particular social group in contemporary Arab communities, and is not spoken natively, has sociolinguistic ramifications. There is no doubt that the Standard variety is accorded the highest status by Arabs, but its esteem and the degree to which it is involved in the course of linguistic change are unrelated. Research shows that linguistic variation and change in Arabic is determined by interplay between local dialects and emerging local or regional standards, independently of Standard Arabic (see Al-Wer, 1997). Educated speakers of Arabic do resort to the use of Standard lexemes and constructions in formal situations. This is largely due to the established appropriateness of the Standard in such domains, and to the fact that learned and specialized lexical items are only available in a Standard form. Outside these situations, educated speakers use the colloquial varieties, and research shows that where linguistic change is in progress away from Standard features, the educated generally lead other groups, in the same way that they lead when the change happens to be in the direction of a Standard feature (for instance, see the results in Jabeur, 1987 and Al-Wer, 1991, and the discussion in Holes, 1995b).

The Dialects

Arabic dialects are the linguistic systems that speakers of Arabic speak natively. They vary considerably from region to region, with varying degrees of mutual intelligibility (and some are mutually unintelligible). Many aspects of the variability attested in the modern dialects can be found in the ancient Arabic dialects in the peninsula (for a detailed description of the ancient dialects, see El-Gindi, 1983). By the same token, many of the features that characterize various modern dialects, or distinguish between them, can be traced to the original settler dialects. In terms of typological classification, Arabic dialectologists distinguish between two basic norms: Bedouin and Sedentary. This classification is based on a bundle of phonological, morphological, and syntactic features that distinguish between the two norms. In the modern, especially urban dialects, it is not really possible to maintain this classification, partly because the modern dialects are typically an amalgam of features from both norms. Geographically, modern Arabic dialects are classified into five groups: Arabian Peninsula (four subgroups); Mesopotamian; Syro-Lebanese (or Levantine, three subgroups); Egyptian (four subgroups); and Maghreb (two subgroups) (for details, see Versteegh, 1997).

Common Dimensions of Variation in Arab Communities

There is a general shortage of studies on variation in Arabic, especially on Arabic in its social setting and in large and heterogeneous urban environments; but this situation is changing. A number of important empirical research studies, utilizing modern methodological and analytical techniques, are in preparation. On the basis of the studies available, it seems that the factors outlined below play important roles in the dynamics of variation and the course of linguistic change.

All variation studies on Arabic mention education as an important social variable, and indeed the findings show that linguistic usage correlates with the level of education of speakers. However, the exact denotation of education as a variable is poorly understood. It is noticeable, for instance, that while level of education of the speaker is used as a sampling tool, it is not integrated in the explanatory model in a consistent way. It is likely that this variable actually symbolizes different aspects of the speakers' characteristics in different communities. It is also likely to be a proxy variable, acting on behalf of such things as contact and exposure to outside communities, especially since in many communities institutions of education are not available locally, and generally the longer individuals spend in formal education the more frequent their contacts become with speakers of other dialects (see Al-Wer, 2002a). In some cases, the type of education, private or public, was found important (as in Haeri's 1997 study in Cairo).

Social class in is not usually used in Arabic studies. A notable exception in this domain is Haeri's (1997) study in Cairo, which analyzes this variable and finds it significant. A forthcoming study on Damascus also uses social class as a sampling and analytical tool. There are two types of urban Arabic communities, which seem to show different corelational patterns. In the well-established urban centers, such as Cairo and Damascus, the original regional, ethnic, or sectarian linguistic distinctions among the population are blurred and do not play a role in sociolinguistic correlations. On the other hand, in the new cities, such as Amman (the capital city of Jordan) and most of the cities in the Gulf region, stratification along ethnic, regional, and sectarian backgrounds are the more relevant criteria for sociolinguistic studies. There are signs that as these cities become established and their new dialects become focused, alternative ways of stratification become necessary. For instance, in Amman, the original distinctions of Jordanian versus Palestinian dialects and urban versus rural Palestinian (which are based on the

regional origins of the city's population), while continuing to be important for an understanding of patterns of linguistic variation among certain groups, are much less important in the speech of the third generation inhabitants of the city. Other, more locally defined criteria, such as socioeconomic class, are becoming significant (for more details, see Al-Wer, 2002b).

Gender has been found to be an important parameter of variation in Arabic. Consistent linguistic differences between male and female speakers are reported in the earlier studies (e.g., Abdel-Jawad, 1981, and Bakir, 1986), as well as in later works (e.g., Jabeur, 1987; Haeri, 1997; Gibson, 1998). Gender is also reported to be significant in studies focusing on code switching and code mixing (e.g., Lahlou, 1992, and Sadiqi, 2002). The interpretation of gender-differentiated patterns in Arabic experienced a complete transformation, although the patterns themselves are consistent and are in keeping with the patterns found in other languages, such as English. In the earlier studies, Arabic was thought to contravene the then generally reported tendency for female speakers to use standard features more often than men, since in Arabic studies men were found to use Standard Arabic features more than women. However, the features that Arab men were found to use more often than Arab women were at the same time characteristic of the localized and in many cases overtly stigmatized varieties, but simply happened to be identical to Standard Arabic features. Since the approach to understanding variation in Arabic has shifted from one based on the assumption that approximation to Standard Arabic features is the governing factor to one recognizing that the target features are characteristic of the *de facto* spoken local standards (which derive their status from the social groups whose speech they represent), the interpretation of gender patterns has also shifted (see Ibrahim, 1986; Haeri, 1987; Al-Wer, 1997).

Within this revised framework, the findings with respect to male-female differences in Arabic communities studied so far suggest that where linguistic change is in progress, allowing for other factors, the female speakers are ahead of the male speakers in the use of newer forms. However, it must be emphasized that the data available from Arabic do not permit us to make generalizations on the basis of gender (to the extent such generalizations can be made for any language). Although there is now a respectable number of sociological studies, mainly in the feminist literature, providing thorough analyses of gender as a social construct in Arab societies, these models have not yet been integrated in studies on linguistic variation in Arabic.

The current generation of students of Arabic linguistics increasingly pays attention to the study of dialect contact. This comes in recognition of the linguistic repercussions of the massive population movements, rapid urbanization, and modernization all over the Arab World. In the established cities, the newcomers largely accommodate to the city dialect (see for instance the results in Jabeur, 1987; Gibson, 1998; Jassem, 1993). In the new cities, various processes of leveling take place and new linguistic forms emerge. There are also signs that regional koineization, transcending political borders, is taking place.

Variation in Child Language

J L Roberts, University of Vermont, Burlington, VT, USA

© 2006 Elsevier Ltd. All rights reserved.

The area of child language acquisition, for the most part, began in the very late 20th century, 40 years after Labov's groundbreaking work investigating the social implications of language variation and change. However, this statement may imply that sociolinguistics is alone in confining language study to adults, when this is not at all the case. Linguistics as a whole, although containing many diverging, and sometimes conflicting, theoretical perspectives, has been virtually united as a field with adults-only content. The purpose of this article is to situate the child in linguistic history, summarize current findings in child language variation, and argue that despite the difficulties and shortcomings of this work, there is interesting and important information to be learned about language from its not-fully-formed speakers, in addition to the more obvious and empirically demonstrated premise that there is interesting and important information to be learned about children from their language.

Historical Overview

Linguistics in the early 20th century was dominated by structuralism. The ways of looking at language structure, which for the most part meant phonological structure, varied, but the emphasis on structure as opposed to history differentiates the linguistics of this period from that of the previous century (Hymes and Fought, 1975: 11). Although language was seen as a 'human function' and a 'cultural function,' the focus was not so much on the speakers as on what was in essence the "product of long-continued social usage" (Sapir, 1921: 4). As such, children were seen as the acquirers of the language of their culture, not as contributors; their acquisition of language was the study of another field – psychology.

It is not the case that children were never mentioned, however. Bloomfield (1933: 29) speculated on language learning, which he called "the greatest intellectual feat any one of us is ever required to perform." Following the highly popular learning theory, he likened the process of language acquisition to forming a 'habit' based on imitation of caretakers' speech. This habit was later shaped and refined by corrections from competent speakers when the child made an error. Bloomfield (1933: 32), in fact, was quite clear on the interests of linguists in this process and noted the following:

> In the division of scientific labor, the linguist deals only with the speech signal (r . . .. s); he is not competent to deal with problems of physiology or psychology. The findings of the linguist, who studies the speech-signal, will be all the more valuable for the psychologist if they are not distorted by any pre-possessions about psychology.

Dialect geographers were similarly occupied with language structure – in this case, its variation across geographic area, whether lexical or phonological or, more rarely, grammatical. Kurath's (1939a, 1939b) large project in the United States was predicated on the assumptions that geographic variation was best reflected in the adult speakers of the community, particularly those who were nonmobile, older, rural, and male (later termed NORMs by Chambers and Trudgill (1980)). Although the origin of these features was of critical importance at the time, it was most likely to be found in the historical settlement patterns and geographical barriers and boundaries of the areas studied (Kurath, 1939a) and not in those young speakers acquiring the dialects.

Chomsky (1957, 1959, 1965) brought children to prominence in the context of learnability. That is, in early versions of generative grammar, the paucity of input to young children was taken as support for the heritability of language. However, these children, like the adult speakers discussed by generative linguists, were more theoretical than real, and it was not until

Variation in Child Language

J L Roberts, University of Vermont, Burlington, VT, USA

© 2006 Elsevier Ltd. All rights reserved.

The area of child language acquisition, for the most part, began in the very late 20th century, 40 years after Labov's groundbreaking work investigating the social implications of language variation and change. However, this statement may imply that sociolinguistics is alone in confining language study to adults, when this is not at all the case. Linguistics as a whole, although containing many diverging, and sometimes conflicting, theoretical perspectives, has been virtually united as a field with adults-only content. The purpose of this article is to situate the child in linguistic history, summarize current findings in child language variation, and argue that despite the difficulties and shortcomings of this work, there is interesting and important information to be learned about language from its not-fully-formed speakers, in addition to the more obvious and empirically demonstrated premise that there is interesting and important information to be learned about children from their language.

Historical Overview

Linguistics in the early 20th century was dominated by structuralism. The ways of looking at language structure, which for the most part meant phonological structure, varied, but the emphasis on structure as opposed to history differentiates the linguistics of this period from that of the previous century (Hymes and Fought, 1975: 11). Although language was seen as a 'human function' and a 'cultural function,' the focus was not so much on the speakers as on what was in essence the "product of long-continued social usage" (Sapir, 1921: 4). As such, children were seen as the acquirers of the language of their culture, not as contributors; their acquisition of language was the study of another field – psychology.

It is not the case that children were never mentioned, however. Bloomfield (1933: 29) speculated on language learning, which he called "the greatest intellectual feat any one of us is ever required to perform." Following the highly popular learning theory, he likened the process of language acquisition to forming a 'habit' based on imitation of caretakers' speech. This habit was later shaped and refined by corrections from competent speakers when the child made an error. Bloomfield (1933: 32), in fact, was quite clear on the interests of linguists in this process and noted the following:

> In the division of scientific labor, the linguist deals only with the speech signal (r . . .. s); he is not competent to deal with problems of physiology or psychology. The findings of the linguist, who studies the speech-signal, will be all the more valuable for the psychologist if they are not distorted by any pre-possessions about psychology.

Dialect geographers were similarly occupied with language structure – in this case, its variation across geographic area, whether lexical or phonological or, more rarely, grammatical. Kurath's (1939a, 1939b) large project in the United States was predicated on the assumptions that geographic variation was best reflected in the adult speakers of the community, particularly those who were nonmobile, older, rural, and male (later termed NORMs by Chambers and Trudgill (1980)). Although the origin of these features was of critical importance at the time, it was most likely to be found in the historical settlement patterns and geographical barriers and boundaries of the areas studied (Kurath, 1939a) and not in those young speakers acquiring the dialects.

Chomsky (1957, 1959, 1965) brought children to prominence in the context of learnability. That is, in early versions of generative grammar, the paucity of input to young children was taken as support for the heritability of language. However, these children, like the adult speakers discussed by generative linguists, were more theoretical than real, and it was not until

considerably later that data from real children were sought (Marcus *et al.*, 1990).

Given this historical context, it is not surprising that when the study of language variation and change as a social, as well as regional, phenomenon began in the mid-20th century, it was with adult or adolescent speakers (Labov, 1966). Despite the very early work of Fischer (1958), whose sample comprised 3-, 5-, and 10-year-old speakers, it was not until more than 20 years later that children younger than the age of 5 years appeared in variation research again. Even then, this work can more accurately be described as a trickle than a flood. In 1981, Kovac and Adamson explored the deletion of finite *be* in African-American Vernacular English (AAVE). This feature of AAVE, along with others, was (and is) a popular topic of variation study (Baugh, 1986; Labov, 1969; Rickford *et al.*, 1991; Wolfram, 1969). Kovac and Adamson, however, were the first to examine the question of developmental versus dialectal variation, a particularly difficult issue to differentiate because the feature in question involved a deletion process that is difficult to distinguish from nonacquisition but important in the study of early dialect learning. The researchers found that although all of their speakers (aged 3, 5, and 7 years) demonstrated deletion, the constraints on deletion were more difficult to acquire. In fact, the children mastered the constraints on copula contraction before those of deletion, which were not fully acquired at age 7 years (Kovac and Adamson, 1981).

Wolfram (1989) studied even younger speakers of AAVE, aged 18–54 months. He too examined a deletion process – in this case, deletion of final nasals with nasalization of the preceding vowel. He found that before age 3 years, the children produced virtually no final nasal segments; after that, however, their acquisitional pattern bore strong relation to that of AAVE, as spoken by adults. That is, /n/ was preferred as a target of deletion over /m/ or /ŋ/, and utterance final /n/ was more frequently deleted than that followed by another word. Finally, the children's patterns of deletion tended to plateau at age 3 years and hold steady, suggesting an acquired and stabilized deletion pattern. Both of these early studies found that the features in question were not clearly apparent in the youngest children. That is, it was not possible to determine if the sparseness of the feature was due to an emerging deletion pattern or an emerging grammatical (e.g., finite *be*) or phonological (e.g., the phoneme /n/) form.

Although these early studies cannot be said to represent a trend toward the study of child language variation, they did set the stage for examining two important questions: What can the study of child language variation tell us about children and the language acquisition process? and What can the study of child language acquisition tell us about language? The first question is far more easily dealt with than the second. The evidence for acquisition can, at times, be directly observed, and although language acquisition is not instantaneous, its progress in individuals is more rapid that the course of language change. Consequently, there are intriguing results that tell us at least the basics of dialect acquisition, whereas the discussion of any implications for language as a whole must be made up primarily of questions.

The Study of Variation and the Language Acquisition Process

Acquisition of language (particularly phonology) is assumed to be a process of movement from babbling to segment and/or rule acquisition. Locke (1983), however, noted that although this process appears to be inevitable in normal acquisition, it is far less easy to document the point of passage from one stage to another with certainty. There is clear agreement that babbling is a natural, physiological process. Deaf children, who have no access to auditory input from caretakers or auditory feedback from their own productions, nevertheless produce babbled sounds in the first year of life. In fact, Locke noted that the movement from babbling to speech is generally assumed to be heavily dependent on 'naturalness' in that those segments that are easier to produce from a physiological standpoint and more frequent in the target language (not necessarily a coincidental pairing) are among the first to be acquired by the child. However, therein lies the complication as well; as Locke (1983: 158) noted,

> If phonological segments and rules can be so 'natural,' it must be difficult indeed to know when a child has 'acquired' a rule, 'learned' an articulation. . . . Such phonological naturalness may blur the separate contributions of biologically innate mechanisms, environmental stimulation, and their modes of interaction.

There is a parallel dilemma in the study of child language variation: at what point does a process such as deletion stop being a stage on the way to mastery of a phoneme or morpheme and become an acquired, but variable, dialectal process? As noted previously, Kovac and Adamson (1981) found that for deletion of finite *be*, the process was still not complete by age 7 years. Their study, however, as well as later ones, demonstrated a possible venue for exploring this 'naturalness' problem. A segment or its deletion may be natural and/or developmental, but the constraints on that process are in some cases language or dialect specific. One definition of acquisition could then be

the presence, absence, or modification of that segment as the speech community requires, not the adult-like articulation of a given segment.

The process of (-t, d) deletion, a subset of final consonant cluster reduction, provides an example. This process, as students of variation well know, allows the deletion of final /t/ or /d/ in word-final consonant clusters. However, the process is constrained by phonological and grammatical environmental conditions, most crucially, in this case, following segment and grammatical form. Although most of the following segment constraints can be seen as a form of simplification, and (following Locke) a child may not be accurately credited for the acquisition of a rule, the constraints of following pause and grammatical form are not examples of simplification. Guy and Boyd's (1990) examination of the grammatical constraint and Roberts's (1997a) study of both phonological and grammatical constraints explored this rule in preschool children. Roberts found that the children age 3 years and older had acquired all the phonological constraints, including that of following pause, and although the specific findings differed slightly, both studies found the children to be in the midst of learning the grammatical constraints. Even the 4-year-olds had not completely acquired the adult rule (Roberts, 1997a).

A study on vowel acquisition revealed similar results. In this case, 3- and 4-year-old children in Philadelphia were studied to determine their progress in learning the short *a* or (æh) vowel (Roberts and Labov, 1995). This feature is complex, with lexical, phonological, and grammatical factors conditioning the raising of short *a* tokens. As was the case with (-t, d) deletion, the children were making excellent progress and had acquired several constraints on short *a*. However, some of the constraints continued to be realized in an inconsistent manner, demonstrating that this phoneme was partially learned, although its articulation was completely mastered by all the children.

As the previous examples demonstrate, the concept of acquisition goes beyond the production of the sounds of speech. This point is not unfamiliar to psycholinguists researching the acquisition of phonology. Locke (1983: 181), in fact, noted that "one may acquire and use forms without necessarily *learning* their precise surface characteristics." He proposed a study in which adults would be compared on their ability to learn a phonetically based and a nonphonetically based rule created by the researchers. However, a rule that is unpredictable unless one knows the dialect of the speaker would seem to be a far better candidate for study than a hypothetical one, and children learning their first language would be more natural subjects. Children who learn that in their speech community /t/ and /d/ are rarely deleted before a pause and short *a* is raised before /ʃ/ but not before /d/ except in the words 'mad,' 'bad,' and 'glad' are learning a linguistic rule or pattern, not relying on a physiological imperative. Systematic variation provides naturally occurring learning and research opportunities that can be of value to both fields of study.

The Language Learning Environment

That children acquire phonemes, rules, constraints, and patterns is a critical point of departure for the study of child variation. However, the outcome of the learning process – a rule acquired or a pattern mastered – is only one facet of this study. It is also important to explore the process by which this learning occurs. What is the language environment from which the child learns his or her community norms? How much of this environment does the child attend to and use?

There is a large body of work on the subject of language learning environments in Western culture (Ferguson, 1977) and others (Ochs and Schieffelin, 1984). In addition to the rich descriptive work these studies provide, they also help to answer the question of the necessity or benefit of a modified language environment for children. This continues to be a subject of debate, but the cross-cultural work cited previously does cast doubt on the necessity of a particular (i.e., mainstream, Western) language learning environment. Whether particular environmental attributes are beneficial to language acquisition is, at least to some extent, dependent on the cultural values of the community. For example, there is evidence that modification of the child's environment as with child-directed speech may lead to faster language learning (Clarke-Stewart, 1973), but whether faster is better is a question to which the answer can vary from one society to another. It is not the purpose of this article to enter into this particular debate, but variation studies can shed light on another aspect of the language learning environment: How does the linguistic environment that children encounter affect their language and its acquisition?

Again, the study of variation can augment what is already known through the study of children's language learning environment. Foulkes *et al.* (1999) studied glottalization in forty 2-, 3-, and 4-year-old children from Newcastle Upon Tyne in England. Their findings on the acquisition of glottalization were similar to those on other variables discussed previously. The children had made progress but not completed their acquisition of the complicated glottal

stop replacement and reinforcement of /t/. In addition, they found that the children demonstrated high degrees of preaspiration when /t/ was in utterance-final position, a pattern that cannot be explained by simplification. Rather, the authors' interpretation was socially based in that they noted that preaspiration was the dominant pattern of young women speakers in the area – those who were also primarily responsible for child rearing.

Roberts (2002) also found evidence of variable patterns in the language environments of young children. This study examined the speech of four white middle-class mothers from Tennessee talking with their toddlers, aged 18 or 19 months, and with an interviewer. These mothers were all speakers of Southern American English, which has as one of its features the pronunciation of long /aɪ/ as in 'time' as a fronted monophthong, or closer to [tæm]. All four mothers used both types of /aɪ/ but produced more of the monophthong /aɪ/ in their speech to the adult interviewer than with their children. The children, therefore, heard child-directed speech that comprised a mix of productions, even though their mothers may have been presenting them with more examples of the nonlocal variant than they typically used with adults. They heard examples of variation: what sounds within their dialect were malleable and in what ways. The previous results suggest that child-directed speech contains the elements necessary for supporting producers of variation at home in their own speech communities.

Although caretaker speech has captured the interest of researchers for decades, one concern about this area of study that has recently become more relevant is the effect of peers, particularly day care peers, on children's speech. This is a particularly important question for variationists because peer effects are basic to variation theory and have always been considered and applied to adolescents and adults. It is this point that has provided the underpinnings for the network analysis by Milroy and others, who have used increasingly specific methods to determine exactly who is the speaker's network. It seems questionable, at best, to work from the assumption that a child's, even a very young child's, network consists solely, or even primarily, of his or her mother. Background information to this effect should be gathered and included in articles written about acquisition of variation. Also advisable are studies that focus on the relative effects of day care and caretaker influence, difficult as these may be to tease apart in the day-to-day existence of children and families.

Early evidence on this point is mixed but generally leaning toward less, rather than more, parental influence. For example, Kerswill (1996) found variable influences in 4-year-olds he studied in Milton Keynes. Some of the children did demonstrate parental effects on dialect learning; others were more influenced by older peers. In any event, the parental influence appeared to disappear by age 8 years. Roberts (1997b) found that parental effects were seen most easily in complicated vowel patterns because children who did not have two native Philadelphia parents did not acquire the complex short *a* pattern. Even on simpler patterns, however, parental effects can be inferred from the finding that children learned most effectively the Philadelphia vowel changes most prominent in their mothers, as opposed to those changes that have been found to be led by males. It is also relevant that the only child to make very limited progress in the acquisition of any of the Philadelphia vowels studied was one with Italian-speaking parents. However, the fact that this child did sound like a speaker of American English, not Italian-influenced English, suggests that peer and other community influences were already at work; his progress on the Philadelphia patterns was simply not as rapid as that seen in the other 3- and 4-year-old children.

Starks and Bayard (2002) also explored this issue with four young speakers of New Zealand English. Their findings echoed many of the previously discussed findings in that the children showed markedly different patterns of acquisition of postvocalic /r/ deletion. Two of the children were virtually nonrhotic from a very early age and two showed considerably more rhoticity, even though all four had rhotic parents and nonrhotic peers. Similar results were found with regard to their acquisition of several New Zealand vowels. The authors suggested that age of entry into day care (and exposure to peers) as well as sibling influence may have been factors in the acquisition differences. Although the study was limited by a small amount of data, it is notable that Starks and Bayard found it essential to perform word-by-word analyses to make sense of the highly variable data.

Some Additional Data

A study of linguistic variation in Vermont (Roberts, 2005) provided an opportunity to explore the day care vs. home linguistic influence on children's replacement of /t/ with glottal stop [ʔ]. This apparently local variant of /t/ is both stigmatized and, unlike other localized productions, enduring in the face of dialect leveling. The data discussed here are a subset of a larger set representing the speech of children and adults. The speech of seven 3- to 5-year-olds was coded as to the use of glottal stop to replace medial and final /t/ in words. All the children were residents of Vermont. Three of them had parents who were not

Table 1 Glottal replacement of /t/ in children with parents who use /ʔ/ and parents who do not use /ʔ/

Child	*Total N*	*/ʔ/ N*	*% /ʔ/*
/ʔ/ parents			
Alice	229	48	20
Jessie	114	15	13
David	55	13	23
Emmy	174	26	14
Non /ʔ/ parents			
Jean	121	6	4
Marie	214	55	25
Cal	174	17	9

glottal stop users. One child's parents were from France and were learning English; one child's single parent was from the mid-Atlantic region of the United States; and one child's parents were originally from Vermont but had extensive travel experience, advanced educational degrees, and a clear dispreference for Vermont speech patterns. The parents of the other four children were Vermonters who, to varying degrees, demonstrated glottal stop replacement of /t/.

It will surprise no one who has read either the previous discussion or the extensive literature on individual differences in child language acquisition (see Bates *et al.*, 1995) that although there were indications of trends of influence present in the results, there was nothing that approached significance in the variable rule analysis of the data. Table 1 shows the results of the comparison between children with parents who demonstrated /ʔ/ replacement of /t/ and those with parents who did not. In general, the children who had glottalization input both at home and at school appeared to do more glottal replacement than those who had this input only at school (where the input was mixed because the teacher was a Vermonter but not all the children came from homes with the same linguistic environment). Strikingly, however, the highest replacement percentage came from Marie, whose input for Vermont speech came from school only. Marie's linguistic background was also the most different from the others because she was the child with French-speaking parents. Although Marie's English was quite good, her parents were insufficiently comfortable in English to consent to be interviewed. This background suggested at least two possibilities for interpreting her glottal stop data. The first has to do with possible overlap between the languages. One of the more popular environments for glottal replacement is word-final /t/ following /n/, as in the word 'Vermont,' which is derived from French. French is well-known to include the deletion of final /n/ and final /n/ plus stop with the nasalization of the previous vowel (Ruhlen, 1978; Tranel, 1968). In Vermont speech, this word and others like it are produced with a nasalized vowel and deleted /n/ followed by /ʔ/ (Roberts, 2005). Although it is not clear from the previous research that /ʔ/ follows the nasalized vowels in French, Locke (1983: 230) noted that word-final nasalized vowels may be perceived, in any case, as preceding a glottal stop. The second possibility is that as Marie was learning the English language as well as the Vermont dialect at school, she was acquiring the Vermont patterns from her teacher (a native Vermonter) and her Vermont peers.

Conclusions are difficult to draw from such small samples. As psycholinguists have found, the process of language acquisition, like that of language change, is a complicated one. Slices of cross-sectional data and group trends are sometimes sufficient only to hint at possible explanations. Continued examinations of even small amounts of data, such as those of Starks and Bayard (2002), are necessary to gain insight into the complexity of child variation.

Conclusion

The study of child variation necessarily combines the disciplines of both psycholinguistics and sociolinguistics. Both fields emphasize process as well as outcome, but the emphasis may take on a different tone in each. In sociolinguistics, the speech of fully formed individuals is used to explore the process of language change. Speakers are assumed to be competent speakers of their particular varieties, and the emphasis is on the change in the variety. In psycholinguistics, fully formed language is used to explore its development in speakers. Speakers (children) are assumed to be moving toward competence, and the emphasis is on the change in the speaker. The challenge for child variationists is to bring together two entities, both of which are in a state of change. It is a difficult challenge because the sociolinguistic methodology, exemplified most often by the interview, necessarily captures a moment in time, both for the language and for the speaker. On the other hand, the collaboration affords the researcher an opportunity to make a contribution to both fields since the assumption that either the language or the speaker is static is an unproven one, at best. The psycholinguist is able to make use of the stable language assumption by focusing on language forms that change so slowly as to be pragmatically immobile: tense and case markings and basic word order. When the focus is on forms that sociolinguists have found to vary (e.g., phoneme production and lexical forms), the more stable mainstream or standard forms are taken as the goal of the language learner. The variationist is able to make use of the stable speaker assumption by focusing on

mature speakers in established speech communities, exemplified by the initial dialectology ideal, the geographically isolated NORMs. The increasing mobility of the population at large and the focus on urban settings and increasingly less isolated rural settings have created a challenge to the stable speaker assumption. It is no longer clear that the speaker, even the mature speaker, resists the linguistic changes brought about by increased mobility.

Child variationists can provide a venue for exploring this new situation: changing language in changing speakers. The studies discussed previously demonstrate both the challenges and the benefits of this work. In summary, we may formulate the following key points that may be useful to variationists:

1. The necessity for close examination of the data of individual speakers, even when group trends are examined. The purpose would be not only to ascertain that individual children are following the documented group trends, although this is critical when working with speakers who exhibit developmental as well as dialect variation. It is also important to explore the very complex pattern of influences on these young speakers and which influences are largest as well as most enduring and, therefore, most likely to influence the process of language change.
2. The importance of exploring the child's network of relationships to document the influence pattern and separate fleeting from long-term influences that may affect not only the speaker but also the language variety.

Of course, neither of these suggestions represents a new methodology. Many researchers examine their data closely to provide interpretive insights that would be lost in group patterns. In addition, network analysis has been practiced in some form since the earliest days of dialect study (Labov, 1966) and continues to be refined (Milroy, 1987). The difference is that the rapidly changing world demographics today coupled with the rapidly changing young speakers make these aspects of method more clearly critical. We are a long way from identifying the ways in which children may influence language change in their own acquisition of that language. However, it is hoped that variationists may benefit from both the methodological and the theoretical results of the exploration.

Variation among Children

Children differ greatly from each other in their rates of learning language, and there are also many reports of differences in the process of acquisition. These differences are relatively well documented for the acquisition of English, but are poorly documented for children learning other languages. In this article, references to variation among children learning languages other than English are to the articles in Slobin (1985) unless otherwise indicated. Lieven (1997) and Peters (1997) contain detailed surveys of the cross-linguistic evidence. Bates *et al*. (1988) report the most detailed longitudinal study of individual differences in the early learning of English, and Fenson *et al*. (1994) provide the most comprehensive cross-sectional overview based on the Macarthur Communicative Development Inventory, a parental report measure.

Variation in Early Comprehension and Production

Children vary considerably in when they first start to show signs of comprehension and when they first start producing words. Because much depends on how comprehension and production are defined, it is difficult to give an exact age range for these activities. Comprehension of individual words such as 'No' starts very early, and of course, children can use contextual cues to interpret the utterances of those around them without necessarily parsing much of what they hear. Although most well-controlled studies of early word learning have found that comprehension is in advance of production, the age range of production is, if anything, even more varied, with some children producing their first words (as reported by parents) at around 10 months whereas others might not produce more than a few recognizable words before 16–18 months (Fenson *et al*., 1994). For most children, progress in comprehension and in production is highly correlated, but there are reports of children whose comprehension outstrips their production by much more than the normal extent (Bates *et al*., 1988). Children who are more than 1 standard deviation (SD) or sometimes 1.5 SD below the mean on standardized tests of language are usually considered to be late talkers. Among this group are children who 'catch up' and join the normal range, as well as a group of children who go on to be defined as having specific language impairment (Rescorla *et al*., 2000). Many studies, though not all, have found that girls tend to start to produce words earlier than boys (Fenson *et al*., 1994). There are also some studies indicating that first-born children start to produce words earlier than subsequent-born children (Fenson *et al*., 1994; Pine, 1995). It is

Comprehension of individual words such as 'No' starts very early, and of course, children can use contextual cues to interpret the utterances of those around them without necessarily parsing much of what they hear. Although most well-controlled studies of early word learning have found that comprehension is in advance of production, the age range of production is, if anything, even more varied, with some children producing their first words (as reported by parents) at around 10 months whereas others might not produce more than a few recognizable words before 16–18 months (Fenson *et al*., 1994). For most children, progress in comprehension and in production is highly correlated, but there are reports of children whose comprehension outstrips their production by much more than the normal extent (Bates *et al*., 1988). Children who are more than 1 standard deviation (SD) or sometimes 1.5 SD below the mean on standardized tests of language are usually considered to be late talkers. Among this group are children who 'catch up' and join the normal range, as well as a group of children who go on to be defined as having specific language impairment (Rescorla *et al*., 2000). Many studies, though not all, have found that girls tend to start to produce words earlier than boys (Fenson *et al*., 1994). There are also some studies indicating that first-born children start to produce words earlier than subsequent-born children (Fenson *et al*., 1994; Pine, 1995). It is

important to emphasize, however, that these group statistics disguise a huge range of variation and that there are very many children who are exceptions to these group averages.

In addition to the timing of comprehension and production and the rate at which children learn, there is considerable variability in the process of early language production. An early stage of relatively accurate matching of a small number of productions of adult words is often followed by a highly individual phase where each child produces a wider range of words, most of which are reduced to a phonological 'template.' The nature of this template varies from child to child, though it always bears a phonological and segmental relationship to the particular language being learned (Vihman, 1996).

There are studies of English and other languages (Hebrew, Danish, Norwegian, Italian, Hungarian, French, Finnish, German, Portuguese) that suggest that children may differ from very early on in the extent to which they pick up on the major tunes of the language or tend to produce shorter and more well-articulated utterances (for detailed summaries, see Lieven, 1997; Peters, 1997). The 'prosodic' or 'tune' strategy involves using chunks of prosodic structure with the prosodic properties associated with questions, attentional utterances, naming utterances, and imperatives. For example, within these intonational envelopes, the child might produce a quite long vocalization with the intonation of a question but with large numbers of schwas and only one or two clear words. Most children will use both strategies, but there are clearly some children who veer toward the extremes of one or the other.

Variation in Early Lexicon and Early Structure

For English-learning children with the same mean length of utterance (MLU), there are large individual differences in the relative proportions of nouns or frozen phrases in their early lexicons (Nelson, 1973, 1981; Lieven *et al.*, 1992). The proportion of nouns is related to the extent to which their caretakers use nouns and elicit the names of objects from the children (Masur *et al.*, 2004). There is also a major debate on whether nouns are predominant in children's early lexicons independently of the language they are learning (suggesting a cognitive advantage for the learning of nouns; see Gentner and Boroditsky, 2001) or whether the proportion of nouns depends on features of the language being learned; for instance, argument drop and agreement marking on the verb might give verbs more prominence (see Choi and Gopnik, 1995). There are also some reports of individual differences in other languages; for instance, in Japanese. The proportion of nouns may also affect how children move into producing longer utterances, with those who have a relatively larger vocabulary of nouns using a more combinatorial strategy, whereas those with relatively more frozen phrases start by producing multiword 'slot-and-frame' patterns (Nelson, 1973; Lieven *et al.*, 1997).

Use of the prosodic or phrasal strategy can result in the child developing prosodic 'placeholders' for particular morphemes of the language (e.g., the determiner slot in English, verbal suffixes in Turkish, or noun class prefixes in Sesotho). Children then start to break down these long prosodic strings and to work out their internal structure (Peters and Menn, 1993; Veneziano and Sinclair, 2000). The combinatorial strategy involves putting words together on the basis of pragmatic, cognitive, or primitive syntactic strategies (Bloom *et al.*, 1975). These strategies may work better for some languages, or some systems in a particular language, than they do for others.

Where verb arguments are relatively unambiguously indicated either by word order or case inflections, children start learning this early, at least for particular verbs. However, there are many languages in which argument marking is mixed or opaque. There are reports of children varying in their relative dependence on case marking or word order in learning Finnish, Japanese, Korean, Serbo-Croatian, and Hungarian. In addition, studies report differences in the degree to which children depend on adult word order (Polish, German, French, Samoan, Korean) and of variability in case marking (Georgian, Japanese, Polish, Italian).

Children (and adults) also vary greatly in the extent of their productivity. This variation can be identified in the overgeneralizations that they make. Some individuals may depend more on item-specific learning, whereas others are more willing to generalize to novel words or constructions (Indefrey, 2002).

Variation in Sentential Operations and Later Syntactic Development

Children can differ in their early placement of the negation marker in English, with some placing it incorrectly in sentence-initial position (*No fit in the box*), whereas others place it correctly from the outset (Slobin, 1985). Maratsos and Kuczaj (cited in Lieven, 1997) also reported that, at a later stage, English-speaking children differ in whether they place the negation marker correctly after the first auxiliary (as in *The boy should not have been eating Jello)* or incorrectly before the main verb (as in *She could have been not sleeping* for *She could not have been sleeping*).

There is considerable variation among children learning English in the degree to which they make uninversion errors in interrogatives (*What I can do?*; Rowland *et al.*, in press). This variation is also reported for inversion after *wo* ('where') in German. There are also reports for other languages that children differ in the scope that they assign to interrogative particles (Hungarian, Kaluli) and in the correct placement of the interrogative marker (for instance, in Hebrew).

In many different languages, some children seem to initially combine clauses using simple juxtaposition; others may use just one unambiguous conjunction, while still others produce the coordinating or subordinating conjunctions (if) required by their language from the outset. These types of variation within and across languages should be an important contribution to the attempt to explain overall patterns of clause combining by appeals to either syntactic or cognitive complexity.

Finally little attention has been paid to individual differences in pragmatic development (for some observations, see Ninio and Snow, 1996; for the effects of friendship group, see Kyratzis *et al.*, 2001) with the exception of gender differences, which are relatively well documented, especially as children grow older (cf. Slobin *et al.*, 1996, Kyratzis and Guo, 2001).

Causes of Variation

Effects of the Input

One major cause of variation among children is the particular input they hear from those around them. However, relationships between characteristics of the input and language development are complex. At a general level, there are relationships between the amount of talking to children and the rate of language learning (Hart and Risley, 1995). In the early stages, there are also relationships between the rate of language development and the ways in which adults use their language: More ostensive speech (e.g., naming objects while looking at a book) and directives related to the child's ongoing behavior (e.g., telling the child, "Put the train over here," while the child is playing with a train) assist learning, whereas attentional directives (saying to the child, "Look at that train," while the child is occupied with something else) seem to be negatively related (Akhtar *et al.*, 1991; Pine, 1992, 1994; Masur *et al.*, 2004).

There are also suggestions of a relationship between the type of input and stylistic differences. Children who exhibit a highly phrasal strategy may be receiving a less 'parsable' input. Thus, Pine (1995) showed that second-born children were significantly more likely to show this strategy than their first-born siblings. Wong Fillmore (1979) reported that this highly phrasal strategy characterized some child L2 learners immersed in a school situation. Brice Heath (1983) reported its use by children in her 'Trackton' group, a working-class African-American group who did not seem to be addressed with the child-directed speech (CDS) typical of more middle-class environments. Finally, Bates *et al.* (1998) reported that her daughter Julia, who had been a classic 'combinatorial' child in her L1 learning, was much more phrasal when learning her L2, Italian, in more group-based situations.

There are also many reports of relationships between the frequency of forms in the input and the order of acquisition of these forms: for instance, the acquisition of English morphemes, verbs, auxiliaries, verb argument structure, and correctly inverted wh-questions. However, the issues are quite complex for several reasons. First, frequency in the input does not guarantee that a child will produce a form: cognitive complexity, saliency, and pragmatic usefulness to the child will also be important. Second, it is one thing for a child to learn a form from the input, but a critical question is how this is related to a more abstract representation of the linguistic system. Over this question there is much debate (see articles by Pine, Richards, and Lieven in Galloway and Richards, 1994, and Tomasello, 2000). An important issue is not just the absolute frequency of particular forms but the type and token relationships between forms and categories (Theakston *et al.*, 2005).

Effects of input are important throughout the language learning process. Huttenlocher *et al.* (2002) showed that children's comprehension of complex syntax was significantly related to the relative frequency with which parents used complex syntax in their speech. The same measure in the speech of their nursery-school teachers was related to children's growth in comprehension over the school year, whereas socioeconomic status was not.

Child-Determined Causes of Variation

The question of whether genetic differences among children could cause differences in language development and, if so, whether this is an effect specific to language or one caused by non-linguistic differences – for instance, by differences in one or more general cognitive abilities – is of considerable complexity and interest. To date, results suggest that there are both genetic and environmental causes of early differences and that, at age 2;0, some of these causes may be specifically related to language skills (Plomin and Dale, 2000). However, there is evidence that genetic

influences on vocabulary and grammar correlate highly at 2;0 and at 3;0 (Dionne *et al.*, 2003) and that, at least by age 4;0, genetic differences in language overlap substantially with genetic influences on individual differences in other cognitive abilities (Colledge *et al.*, 2002).

There seem to be clear differences among children in their willingness to generalize and overgeneralize: Thus, Abe was not only the 'master' of past tense overgeneralization (Maratsos, 2000) but he also produced relatively large numbers of feminine non-nominative subject pronouns (*her*) with agreeing verbs (e.g., *her has a tummy ache*; Pine *et al.*, 2005). This difference in children's willingness to 'linguistically risk take' is quite well documented, and such a willingness to take linguistic risks may characterize children who learn the language very quickly. It has been suggested that linguistic risk taking may be related to a more general 'risk-taking' strategy on the part of some children, but this has not been well researched.

Gender differences in the rate of language development are well documented, certainly for the later stages and, in many studies, for early acquisition as well (Fenson *et al.*, 1994). Boys are also over-represented in groups of late talkers, those with specific language impairment, and stutterers.

Finally there have been a number of suggestions in the literature that varying language acquisition strategies could arise from neuropsychological differences in the brain. For instance in those who are left lateralized for language, the right hemisphere (RH) is more concerned with musical representations, whereas the left, as is well established, subsumes language. There are theories that suggest initial language learning occurs in the RH, which is then taken over by the left hemisphere, and that differences among children reflect the extent to which they continue to use the RH to analyze language. Very much more basic neuropsychological work needs to be done before it would be possible to test these hypotheses successfully (for an outline, see Shore, 1995).

Conclusions

All theories of language development need to be able to account for the range of variation that children show. The pervasive effects of the input, including different types of frequency, must be incorporated; these effects make it difficult to sustain explanations that depend simply on the child hearing small numbers of examples of each structure. Dismissing variation among children as 'noise' involves throwing out of consideration crucial data for developing a psychologically realistic account of the process by which children the world over learn language.

Variation in French

J Auger, Indiana University, Bloomington, IN, USA

© 2006 Elsevier Ltd. All rights reserved.

Introduction

The study of variation occupied a central place in the early development of French linguistics. For instance, the pioneering work of Jules Gilliéron for the *Atlas linguistique de France* at the turn of the 20th century has had a major impact on dialectology. Similarly, the work of Louis Gauchat on the social variation observed in a small Swiss village at the beginning of the 20th century may well be the earliest study of variation within a single speech community.

While geographical variation continues to play an important role in distinguishing speakers from different parts of the French-speaking world or even from different regions, this article will focus on social variation. However, the geographic dimension will be evoked through the comparison of variation studies in different communities. Rather than attempt to superficially describe a large number of variables, this article will examine a few variables that have been investigated in numerous speech communities and

will discuss their significance for a better understanding of the links between language use and social structure.

Social Variation

Many linguists consider that variation within a single community must be a reflection of contact with neighboring communities, incomplete acquisition of a certain dialect, or some other irregularity that disrupts the homogeneity that is considered to be normal. Because most communities have regular contacts with their neighbors and include members who grew up elsewhere, dialect contact can be plausibly invoked as an explanation for many variable patterns. However, the early work of Gauchat (1905) establishes that linguistic homogeneity may very well never exist. Gauchat investigated the speech of the Swiss village of Charmey precisely because this isolated village could be expected to provide a prime example of an invariant and unified language. Based on his investigation of the speech of women and men of all ages and from the different sections of the village, Gauchat concluded that there was no such uniformity. Even after excluding some forms of variation that could be attributed to language or dialect contact, Gauchat identified five phonetic variables for which no such explanation was available. For instance, he noticed that there was a tendency among some speakers to monophthongize /aᵒ/ or, on the other hand, to diphthongize /e/. He also noted a tendency to pronounce /θ/ as [h]. For these variables, he reported that younger speakers used innovative variants more often than older speakers and that members of the middle generation used both older and innovative forms. He also noted a tendency for women to use the innovative pronunciations more often than men. Gauchat, who attributed the social distribution of these pronunciations to change in progress, saw his analysis largely confirmed by Hermann (1929), who revisited the same village years later and observed that many variables had progressed in the direction predicted by Gauchat. Very interestingly, though, Hermann also established that not all variation is a reflection of change in progress, because one variable, the aspiration of /θ/, had remained stable in the community. The contrast between this stable variable and the others provided an early illustration of an important generalization made by Labov (1990) concerning the linguistic behavior of women and men: in situations of change in progress, women tend to be ahead of men and use larger proportions of innovative variants, while in stable variation, women tend to use more prestigious forms than men.

Despite the pioneering work of Gauchat, we must note that variationist sociolinguistics has not had a very strong impact in France, Belgium, and Switzerland (Armstrong, 2001: 2; Bauvois, 2002: 9; Gadet, 2003). On the one hand, very few continental linguists have adopted the Labovian approach in their studies of phonetic or phonological variation. Bernard Laks' (1977, 1983) work on phonological variation in the speech of Parisian teenagers, Anne Lefebvre's (1991) investigation of phonological variation in the French of Lille, and Cécile Bauvois' (2002) study of phonological variation in the French of Mons in Belgium constitute noteworthy exceptions. On the other hand, there has been much resistance on the part of French linguists against the use of variationist methodology for the study of variables above the levels of phonology and morphophonology. Claire Blanche-Benveniste and the members of her *Groupe aixois de recherche en syntaxe*, as well as many colleagues in other parts of France, have argued that while they have no difficulty accepting the fact that pronouncing *table* with or without a final /l/ or *père* 'father' with an apical, a velar, or a uvular /ʁ/ does not change the linguistic meaning of the word, the same assumption does not hold for alternations such as the choice of the auxiliary in compound verbs, as in (1), or the choice of mood in subordinate clauses, as in (2).

(1a) Parce qu'on a parti nous-autres, le 29 avril
because one has left us others, the 29 April
'Because we left, us, on April 29' (Sankoff & Thibault 1977: 86)

(1b) On est parti à 11heures du matin
one is left at 11 o'clock of-the morning
'We left at 11 in the morning' (Sankoff & Thibault 1977: 86)

(2a) faudrait que j'en
would-be-necessary that I of-it
enlèverais
remove. CONDITIONAL
'I should remove some' (Auger 1990: 87)

(2b) faudrait que l' professeur
would-be-necessary that the teacher
sache ce
know.SUBJUNCTIVE that
que l' enfant a besoin
that the child has need
'the teacher should know what the child needs' (Auger 1990: 88)

The rest of this article will show that variationist sociolinguistics has found a much more fertile ground in French-speaking Canada and among American, British, and other foreign scholars who do research on French, as well as with French scholars living in North America.

Phonological Variation

While regional and social varieties of French are characterized by specific features that distinguish them from other varieties (e.g., palatalization in words like *quai* [tʃɛ] 'wharf' in Acadian French or vowel devoicing in words like *dépité* [depi̥te] 'greatly vexed' in Québec French), numerous variable phenomena are commonly found in many, if not all, communities. The investigation of such variables has revealed that, even though frequency of use and some details in the favoring factors vary across communities, many aspects of the variation are shared by all French speakers.

It is probably safe to say that /l/-deletion characterizes every variety of French. While its frequency varies across linguistic contexts and groups of speakers, it is difficult to imagine a French speaker who never deletes /l/ in third person subject pronouns in sentences such as (3)a. In addition, for many speakers, /l/-deletion can affect object pronouns and definite determiners, as shown in (3)b,c. Even though /l/ can also be deleted in other environments, such as in the words *plus* 'anymore' and *quelque* 'some' or in word-final consonant clusters in words like *table* 'table,' these contexts constitute variables of their own and are consequently studied separately from the grammatical words listed in (3). (Unless otherwise specified, the phonetic transcriptions provided for all examples correspond to colloquial Québec French.)

(3a) Il mange [ilmãʒ] ~ [imãʒ]
he eats
'He eats'

(3b) Je les vois [ʒlevwa] ~ [ʒevwa]
I them see
'I see them'

(3c) Tu vois la fenêtre [tˢyvwalafnɛ:t] ~ [tˢyvwaafnɛ:t]
you.sg see the.fem window
'You see the window'

All communities in which this variable has been investigated (e.g., Montréal, Sankoff and Cedergren, 1971; Tours, Ashby, 1984; Ottawa-Hull, Poplack and Walker 1986; Lorraine, Armstrong, 1996) share the following characteristics. First, /l/ deletion is not a purely phonological phenomenon. As shown by Sankoff and Cedergren (1971), in phonologically identical environments, /l/ deletion can affect pronouns and determiners, but never an /l/ that is part of a lexical word; cf. (4). Similarly, while /l/ deletion is possible in the weak subject pronoun *elle* 'she,' it is not allowed in the corresponding strong pronoun, as seen in (5). Second, deletion is most frequent in subject pronouns, less so in object pronouns, and least frequent in determiners. Among subject pronouns, *il(s)* favors deletion more than *elle(s)*, and impersonal *il* 'it' most favors deletion. Finally, deletion in subject pronouns is favored before consonants more than before vowels.

(4a) à la veille [alavɛj] ~ [a:vɛj]
to the verge
'on the verge'

(4b) à laver [alave]/*[aave]/*[ave]
to wash

(5) Elle, elle prie [ɛlapʁi]/*[ɛapʁi]/*[aapʁi]
she she prays
'SHE prays'

The fact that so many communities share the pattern of /l/ deletion just described can be attributed to the history of /l/ deletion in French. We know that /l/ deletion in *il(s)* before a consonant is attested at least since the 16th century and that it affected *elle(s)* only later, due to the fact that a word-final schwa used to protect the /l/ in that word. /l/ deletion in determiners and object pronouns appears to have started later, because this phenomenon is not mentioned in studies of colloquial European French and Oïl languages consulted by Bougaïeff and Cardinal (1980: 94).

While all communities investigated share the basic pattern described here, interesting differences distinguish individual communities. For instance, /l/ deletion is so frequent in *il(s)* in Canadian French that Poplack and Walker (1986: 182) posited that "these pronouns have been relexicalized as [i], and that any realizations of [l] in them are cases of reinsertion." In European French, on the other hand, the phonological pattern that favors /l/ absence before consonants more than before vowels makes a deletion analysis plausible (Ashby, 1984: 8). Another difference concerns the phonological context that favors deletion in object clitics and determiners. While this phenomenon is essentially intervocalic in Canadian French (Sankoff and Cedergren, 1971: 1110 and Poplack and Walker 1986: 175), Ashby (1984: 8) found that a preceding consonant favors deletion more than a preceding vowel in object clitics, a difference that is consistent with the idea that /l/ deletion in object clitics developed independently on the two sides of the Atlantic ocean. The age distribution of /l/ deletion also differs. In Canada, all age groups exhibit similar rates of /l/ deletion, which suggests that /l/ deletion in Montréal and Ottawa-Hull French is an example of stable variation. In France, however, Ashby (1984) reports that young speakers delete /l/ in subject and object clitics more often than older speakers, as can be seen in Table 1, and he has attributed this pattern to a change in progress.

Table 1 The effect of age on /l/ deletion in Tours French

Factor	*N*	*Relative frequency*	*Varbrul probability*
Subject clitics			
14–21 years	1506/1792	84%	.687
51–64 years	1322/1951	68%	.313
Object clitics			
14–21 years	30/103	29%	.676
51–64 years	17/187	9%	.324

Based on Tables 4 and 5 in Ashby, 1984.

Morphosyntactic Variation

While teachers spend considerable time trying to eliminate what they consider ungrammatical elements from the speech of their students, a quick examination of any corpus of spoken French reveals that, at best, their efforts manage to ensure that such condemned forms alternate with their standard equivalents in the speech of many speakers. For instance, in conditional clauses introduced by *si* 'if,' speakers frequently use the conditional mood instead of the prescribed imperfect tense, as illustrated in (6). Similarly, in subordinate clauses introduced by a main verb in the conditional, the prescribed subjunctive is often replaced by a concordant conditional verb, as we saw in (2). Another such alternation is that between *avoir* 'to have' and *être* 'to be' as auxiliaries with verbs that, according to French grammars, require the *être* auxiliary, as in (1).

(6a) C'est comme si j'dirais
it is as if I say.CONDITIONAL
'J'espère qu 'i a ben faite.'
I hope that he has well done'.
'It's as if I said 'I hope he did the right thing' (Lepage 1988: 112)

(6b) c'est comme si i venait fou ou
it is as if he came crazy or
ben euh tsé i avait peur
well uh you-know he had fear
'it's as if he became crazy or was afraid' (Lepage 1988: 112)

Other variable patterns that are common throughout the French-speaking world involve two elements that are considered grammatical in French. One example is the expression of future tense. French possesses an inflected future tense, as shown in (7)a, and a periphrastic construction consisting of the verb *aller* 'to go' followed by an infinitive verb, as illustrated in (7)b.

(7a) On se mariera pas.
one self will-marry not
'We won't get married'
(Poplack & Turpin 1999: 141)

(7b) quand tu vas te marier
when you.sg go yourself marry
'when you get married'
(Poplack & Turpin 1999: 141)

According to traditional grammars and many linguists, the inflected and the periphrastic forms both exist in French for the purpose of expressing different views of future events. The periphrastic form is often said to refer to events that will take place in the near future, that are certain to take place, or that result from current preparations, while the inflected future encodes events that are more distant or less certain. Jeanjean (1988) analyzed 450 tokens of both forms of the future in hexagonal French and proposed that a number of morphological criteria determine which future form is appropriate in any given occurrence. However, many variationists who have investigated the use of both verbal forms in corpora of natural speech have found that while some contexts require one or the other future, there are many contexts in which both the inflected and the periphrastic forms can be used without any change in meaning. This is shown in an example like (8) where both forms of the future refer to a choice that the speaker must make that does not involve different time frames or degrees of certainty.

(8) J'me pose la question. Si j'vas
I me ask the question. If I go
l'reprendre ou si j'le
him take-back or if I him
reprendrai pas.
will-take-back not
'I ask myself the question. Whether I will take him back or not.' (Deshaies and Laforge 1981: 28)

Poplack and Turpin (1999) investigated the variation between the two future tenses in the French of Ottawa-Hull, an urban area at the border of Ontario and Québec. Like previous studies of future expression in spoken Québec French (Deshaies and Laforge, 1981 and Emirkanian and Sankoff, 1985), Poplack and Turpin found that the periphrastic future is by far the form used most often to encode future events, with 73% of all tokens, compared to 20% of tokens in the inflected future and 7% for the present. Their study also revealed that while both futures can be used to express the same meaning, their distribution across contexts is quite unequal. Table 2 summarizes the results of their study. It shows that, contrary to what might be expected on the basis of the meaning differences commonly prescribed for the two future tenses, the choice between inflected and periphrastic future does not differ much with distal and proximal futures: both forms are slightly favored for verbs expressing events that will soon take place and slightly disfavored for expressing events predicted to take place in a more distant future. However, this result does not mean that

Table 2 Probabilistic analysis of future tense expression in Ottawa-Hull

	Inflected future	*Periphrastic future*
Total N for each variant	725	2627
Temporal distance		
Proximal	.52	.56
Distal	.48	.43
Type of adverbial specification		
Nonspecific	.85	.19
No adverbial	.47	.56
Specific	.37	.23
Contingency		
Contingent	.51	not significant
Assumed	.45	
Grammatical person		
Formal *vous*	.81	.22
Other	.49	.51
Negation		
Negative	.99	.01
Affirmative	.36	.65

Based on Table 3 from Poplack & Turpin 1999: 149.

this meaning difference has entirely disappeared from the French spoken in Ottawa-Hull; instead, the strong favoring effect of nonspecific adverbial complements such as *tôt ou tard* 'sooner or later' or *un jour* 'some day' for the inflected future and the concomitant disfavoring effect for the periphrastic future indicate that such an association still influences the choice of future tense. The most powerful factor influencing tense choice is whether the clause is affirmative or negative; a negative clause strongly favors the inflected future, while an affirmative clause strongly favors the periphrastic future, as is illustrated in (8). Finally, the more formal status of the inflected form can be seen in the fact that the formal pronoun of address *vous*, used to address a single person to whom we must show respect, is the only grammatical person that favors the inflected future.

While no quantitative studies of the future tenses in European French allow us to compare future tense usage on the two sides of the Atlantic ocean, a recent study of future expression in Acadian French by King and Nadasdi (2003) revealed that the two tenses have evolved quite differently in the two varieties of Canadian French. The inflected and periphrastic futures are used with almost equal frequencies in the three Acadian communities investigated by King & Nadasdi: 53% for the inflected future and 47% for the periphrastic future. It thus appears that the strong decline in use of the inflected future observed for Québec French cannot be considered to be a general characteristic of Canadian French. In addition, the results of the variable rule analysis presented in

Table 3 Periphrastic future usage in Acadian French

Factor	*Factor weight*	*%*	*N*
Temporal reference			
within hour	.689	78%	70/90
within day	.644	72%	36/50
within week	.678	71%	35/49
longer than week	.479	40%	176/442
continual	.135	11%	6/54
Certainty			
certain	.695	72%	178/246
uncertain	.387	33%	145/439
Presence of subordinate clause with *quand*			
no	.511	48%	321/669
yes	.132	13%	2/16

Based on Table 2 in King & Nadasdi 2003: 334.

Table 3 indicate that negation, which is the most powerful factor in favoring use of the inflected future in Québec French, plays no significant role in Acadian French. Similarly, type of adverbial specification, contingency, and grammatical person, which all play a significant role in Poplack and Turpin's study, do not significantly affect variant choice in Acadian French. Instead, temporal reference, which plays a relatively minor role in tense choice in Ottawa-Hull French, most significantly affects the choice between the two future tenses in Acadia: the periphrastic future is favored for events that will take place within the near future but its probability of use decreases with more distal and continual events such as *Ils fumeront jusqu'à leur mort* 'They will smoke until their death.' The fact that degree of certainty that an event will take place and presence of a subordinate clause introduced by *quand* also influence choice of tense suggests that the two future tenses retain the meanings described in many grammar books.

Variation and Change

One of the major contributions of variationist sociolinguistics has been the tools it has developed to examine the gradual progression of innovative linguistic forms in a speech community. The concept of apparent time, which attributes differences across generations to the fact that their speakers have acquired their linguistic competence at different times and assumes that their speech continues to reflect the linguistic system to which they were exposed and which served as input for their own grammar, has allowed sociolinguists to identify many instances of change in progress. Research in real time, that is, using corpora recorded at different times, has confirmed the validity of the apparent-time concept.

Research on variation in French has greatly contributed to improving our understanding of the progression of innovative forms.

Loss of Negative *ne*

Verbal negation in standard French is doubly marked: the verb is preceded by the particle *ne* and followed by a negative adverb (most often *pas* 'not,' but also *plus* 'anymore,' *jamais* 'never,' etc.) or quantifier (*rien* 'nothing,' *personne* 'nobody'), as can be seen in (9). However, in spontaneous speech the *ne* is often absent, as illustrated in (10).

(9a) Je ne connais pas la réponse
I NEG know not the answer
'I don't know the answer'

(9b) Vous n' avez vu personne
you.pl.NEG have seen nobody
'You haven't seen anyone'

(10a) Je Ø connais pas la réponse

(10b) Vous Ø avez vu personne

The first variationist analysis of *ne*, that of Ashby (1976), investigated *ne* deletion in the speech of 50 speakers from the Parisian upper-middle class. It revealed that *ne* is deleted almost as often as it is uttered, with a deletion rate of 44.1%, a rather shocking finding for speakers assumed to speak 'standard French.' Sankoff and Vincent's (1977) study of *ne* deletion in Montréal French, revealed an even lower rate of *ne* usage, because they found only 46 unequivocal cases of *ne* in a sample of 10 000 negative sentences, or a 99.5% deletion rate. This rate of omission for *ne* far exceeds the omission rates varying between 25% and 86% that had previously been reported for European French. If the French language is currently losing *ne* and moving toward a system of verbal negation that relies exclusively on a post-verbal negative element, Montréal appears to be ahead of other communities. However, Sankoff and Vincent do not think that *ne* has become a foreign element for Montrealers. Based on the fact that most instances of *ne* in their corpus are associated with discussions of formal topics, they propose that *ne* constitutes a syntactic resource available to all speakers that continues to play an important stylistic role; consequently, they do not predict that it will completely disappear from Montréal French.

Ashby (1981) investigated the possible loss of *ne* in the French city of Tours. Based on a sample of 35 speakers representing two age groups (14–21 years and 51–64 years) and three socioeconomic classes, Ashby found a deletion rate of 63%. Like Sankoff and Vincent, his sample contained no speakers who never deleted *ne*; however, contrary to their study, only one speaker categorically deleted *ne* (45 out of 60 categorically deleted *ne* in Sankoff and Vincent's study). Ashby also showed that *ne*-deletion is more frequent in informal style and thus carries a stylistic meaning similar to that uncovered by Sankoff and Vincent in Montréal.

Table 4 *ne* usage in Tours French in 1976 and 1995

Date	*Relative frequency of* ne *usage*	*Absolute frequency of* ne *usage*
1976	37%	1031/2818
1995	18%	346/1891

Based on Ashby (2001: 9).

Ashby's investigation of age, socioeconomic status, and gender reveals that not all speakers are equally likely to delete *ne*. Based on the fact that deletion is more frequent among young speakers and that the age difference is visible within each socio economic class and each gender, Ashby (1981: 683) concludes that "the relative distribution between the two age strata strongly suggests that the particle is being lost in contemporary spoken French" and that this is a probable case of change from below led by working-class women. Blanche-Benveniste and Jeanjean (1987) challenged Ashby's conclusion, pointing out that *ne* deletion was already attested during the 17th century and attributing the linguistic behavior of the two generations of speakers instead to the fact that young people use colloquial speech more easily than older persons, who tend to use their 'Sunday French.'

In response to the challenge posed by Blanche-Benveniste and Jeanjean, Ashby returned to Tours in 1995 and collected a new corpus (Ashby, 2001). In order to ensure that his new data were comparable to his early data, Ashby used the same interview methodology and recorded 25 speakers belonging to the same age ranges. He also sought speakers whose social profiles corresponded as closely as possible to those of his first subjects. As Table 4 shows, the overall rate of *ne* usage greatly decreased during the 19 years that separate Ashby's two corpora: 37% in 1976 vs. 18% in 1995. The social differences observed in the 1976 data are replicated in 1995, the only difference being that the maintenance rates are consistently lower in 1995 than in 1976, as we can see in Table 5. While older speakers continue to use *ne* more frequently than younger speakers, the fact that their rate of usage in 1995 is half of what it was in 1976 does not support Blanche-Benveniste and Jeanjean's hypothesis that the generational difference observed in Ashby's initial study must be attributed to age grading. Ashby's conclusion is further strengthened by a comparison of the speech of 11 speakers

Table 5 Social distribution of *ne* usage in Tours French in 1976 and 1995

	1976	*1995*
Socioeconomic status		
A	45%	26%
B	47%	17%
C	15%	9%
Gender		
Men	42%	20%
Women	30%	17%
Age		
51–64	52%	25%
14–22	19%	14%

Based on Tables 5, 6, and 7 in Ashby (2001).

who were interviewed both in 1976 and in 1995; these data show that, apart from two speakers who have experienced significant social mobility and increased their use of *ne*, all subjects have either retained similar rates of *ne* usage or decreased their usage.

Many studies have investigated *ne* deletion in various communities of French speakers and report patterns of linguistic and social conditioning similar to those uncovered by Ashby and Sankoff and Vincent (e.g., Coveney, 1996; Pooley, 1996). Additional evidence in favor of change in progress comes from Armstrong and Smith's (2002) study of real-time change in radio speech. Their analysis compares patterns of *ne* deletion in excerpts drawn from journalists, writers, and politicians who were recorded in 1960–61 and in 1997. Not surprisingly, *ne* is deleted in radio speech much less frequently than in corpora of sociolinguistic conversations. Interestingly, though, their data reveal that radio speech is also affected by the change that appears to be taking place in France. Indeed, while they recorded a rate of *ne* deletion of 7.4% in the 1960–61 corpus, this rate increased to 27.5% in the 1997 corpus, a difference that is very highly statistically significant.

Conclusion

Space constraints have forced us to focus on a few variables that illustrate both the intricate patterns of linguistic and social conditioning that govern variation in specific communities and across communities and the similarities and differences that characterize the different speech communities. However, interested readers should be aware that many more variables have been investigated (e.g., schwa deletion, liaison, first person plural subject pronouns, pronouns used for indefinite reference, strong plural pronouns, subject doubling, auxiliary, discourse markers, etc.). We would like to now point to other research programs in which scholars studying French have played central roles.

Most of the studies reviewed in this article have focused on urban communities in which French is the language spoken by the majority of the population. Many francophone communities in North America are located in rural areas and/or in regions in which English is the language of a majority of speakers. Obviously, such communities must be approached differently. For instance, in many rural communities, socio economic class is too uniform across speakers to be expected to influence the linguistic choices of speakers. In communities of this type, social networks and attitudes toward one's community often play a central role, as shown, for instance, in the work of Louise Beaulieu on Acadian French. In minority communities, the amount of French used by native speakers varies greatly, another factor that we can expect to influence their linguistic production. Raymond Mougeon and his colleagues, who have investigated the French used by teenage native speakers in five different towns in Ontario, have confirmed that, for many variables, degree of restriction of language use closely correlates with the language patterns of different speakers. Their analyses show, for instance, that some variants typical of colloquial speech are underused by teenagers who make very limited use of French outside of school, while other variants, absent or rare in the speech of speakers who regularly use French but frequent in the speech of restricted speakers, reflect a less than perfect mastery of their mother tongue.

Another area in which research on French has made a great contribution is second-language acquisition. In recent years, many scholars have turned their attention to the acquisition of variable patterns. After years of studying patterns of variation in native speakers of French in Montréal, Gillian Sankoff and Pierrette Thibault have shifted their attention to the study of bilingual English speakers from the same city to determine whether these speakers share the same patterns as native speakers. Other researchers (e.g., Raymond Mougeon working on French-immersion students in Ontario, Vera Regan focusing on Irish learners of French, and Kelly Sax looking at American students from a Midwest university) have shown that while learners acquire some aspects of the variable patterns characteristic of native speakers, experience living among them better helps learners master the intricate patterns of linguistic and social conditioning better than extended classroom learning.

In the chapter "Is there a French theory of variation?" Gadet (2003: 35) concludes: "Those linguists who do not see themselves specifically as variationists are in fact the ones who have most furthered the study

of variation." This article challenges that position. While it is true that few French linguists have adopted the variationist framework in their study of variation, the detailed investigations of an international team of researchers have greatly contributed to advancing our knowledge of the variable patterns that characterize the French language in many of its communities.

Variation in German

S Barbour, University of East Anglia, Norwich, UK

© 2006 Elsevier Ltd. All rights reserved.

An examination of German immediately reveals unusual geographical and social variation in the language. Varieties labeled as *deutsch*/German are often not mutually intelligible, as witnessed by the use of subtitles in Swiss-German films shown to audiences in Germany. German-speakers regularly report comprehension difficulties when visiting German-speaking areas distant from their homes. There is a good case for seeing German as the most variable language in Europe.

German in Geopolitical Context

German includes most of the Continental West Germanic dialect continuum that, before the Germans lost territory in the 20th century, stretched from Dunkirk in France to beyond Vienna and beyond Königsberg/Kaliningrad in East Prussia (now in the enclave of Russia between Poland and Lithuania). Beyond that continuum are, or were, enclaves of German speech in most Central and Eastern European countries and in the former Soviet Union, as far away as Kazakhstan and Siberia. By 'dialect continuum,' I mean a language area where basilectal dialect speech changes slightly from place to place over a wide area, with perhaps noticeable differences even from one village to the next, with poor comprehensibility between the speech of places fifty to a hundred kilometers apart, and with possibly no comprehensibility between the varieties at the ends of the continuum. Such continua may include several languages, for example, Western Romance (including French, Catalan [Catalan-Valencian-Balear], Castilian Spanish [Spanish], Italian, Portuguese, Occitan [Auvergnat, Gascon, Languedocien, Limousin], and others) or South Slavonic (including Slovene [Slovenian], Croatian [Serbo-Croatian], Serbian [Serbo-Croatian], Macedonian, and Bulgarian).

Although comparable in size and in variability to the Western Romance and South Slavonic continua, the Continental West Germanic continuum is unusual because in the minds of most speakers of the relevant dialects, it includes only two languages, German and Dutch. One of these, German, occupies the overwhelmingly greater part of the territory in question and exhibits virtually the full range of variability found in the continuum. Other large continua in modern times have been divided into a greater number of distinct languages as the people in question have become divided into religious, regional, cultural, and ethnic groups, in other words, nations. Occupying different parts of the continuum's territory, such groups then developed the concept of distinct languages, linked to distinct processes of standardization. One only need think of Western Romance divided into the clearly distinct French, Spanish, Italian, and Portuguese (and others).

Some speakers of different languages within continua may be quite unaware of their continuum's existence, but speakers of German often see the Continental West Germanic continuum clearly, even seeing its division into Dutch and German as anomalous. It is not uncommon to find speakers of German who regard Dutch as a German dialect. An outside observer well versed in the Continental West Germanic linguistic situation will not see the separation of Dutch as a distinct language as anomalous. For this observer, the contentious questions lie elsewhere: (1) in the development and persistence of the idea of a single language within the greater part of the large and linguistically diverse Continental West Germanic continuum; (2) in the development of the idea of a single nation, Germany, in such a large, diverse geographical area and in such a diverse population; (3) in the slow, incomplete, and fraught separation between Germany and Austria, with its parallel linguistic separation falling far short of a division into different languages; (4) in the development of a kind of linguistic independence in German-speaking Switzerland that is mainly found in spoken language; (5) in the development of a distinct but closely related language in Luxembourg that plays a role (along with French) in national identity; with German, fulfills important utilitarian functions in Luxembourg; (6) in the strong persistence of regional and local dialect in the entire German-speaking area, particularly in the Centre and South; (7) in the strong significance, despite its diversity, of the language for German national identity, but also for Austrian national identity; and (8) in the occurrence of a small number of West Germanic Frisian dialects in the northwest, spoken by bilinguals who also use either Dutch or German – the Frisian dialects not being part of the continuum.

The main points of interest in the part of the Continental West Germanic continuum known as German are (1) the scope of dialectal diversity; (2) the relationship between the standard language and other varieties; and (3) the variation within the standard language. Fuller discussion of the tension between the diversity of German and its role in national and ethnic identity and the complex relationships between German and other languages can be found elsewhere, for example in Clyne (1995),

Barbour and Stevenson (1990: 23–54), Barbour and Stevenson (1998: 25–59), and Barbour (2000a).

Dialekt, Colloquial, and Standard Varieties

When discussing dialectal diversity in German, it is important to understand that 'dialect/*Dialekt*' in works on German sociolinguistics usually means basilectal dialect, in other words, the regional dialect that is maximally distinct from the standard language. This contrasts with the usage of 'dialect' in English to indicate any form of a language that differs appreciably in grammar or lexicon from other forms of the language. 'Dialect' in this sense in English may or may not include the standard language. For the sake of clarity, in this article 'dialect/*Dialekt*' in the German sense will be referred to as 'traditional dialect.' Where such traditional dialects as recorded in the early 20th century, or before, have now been radically modified or replaced, German works may describe the area in question as 'free of dialect.' This could suggest to a non-German reader a place where everyone speaks the standard language, which is virtually never the case. In such areas, and elsewhere, a great deal of speech lies between the standard language and the traditional dialect; in German it is labeled *Umgangssprache*, which I term 'colloquial speech.' Such colloquial speech includes varieties that, in English would be termed 'dialect,' at one end of the scale, or 'informal or colloquial standard language,' at the other. For the sake of clarity, I divide colloquial speech into 'colloquial standard language' and 'colloquial nonstandard language'; the latter generally corresponds to 'dialect' in works written in English. [This terminology is outlined in full in Barbour and Stevenson 1990: 133–146; also see Barbour 1999).] In German sociolinguistics there has been relative neglect of colloquial language, exceptions being the work of Jürgen Eichhoff (1977, 1978) and of some East German scholars such as Helmut Schönfeld (see Barbour 2000b); this neglect extends to registers that I am labeling 'colloquial standard language.' Work on German 'standard language' (*Standardsprache* or *Hochsprache*) tends to refer chiefly to the rather more formal registers, which I discuss here as 'formal standard language.'

This article will compare traditional German dialects with the formal standard language, following the common assumption that other forms of the language represent compromises between these two ends of the spectrum of variation. Since this assumption is very crude and incorrect in many matters of detail, more detail on other varieties (and hence, corrections), will be provided as necessary.

Our discussion will start with phonetics and phonology (sounds), moving on to the morphology of the noun phrase and of the verb phrase. Except where otherwise stated, further detail about all of the phenomena discussed can be found in Barbour and Stevenson (1990: 55–99, 133–180); Barbour and Stevenson (1998: 60–107, 145–198); and Russ (1989).

German Dialect Continuum

Descriptions of German dialects almost always divide the dialects into three geographical groups: Low German/*Niederdeutsch*, Central German/*Mitteldeutsch*, and Upper German/*Oberdeutsch*. Central German and Upper German may be grouped together as High German/*Hochdeutsch*, these last two terms being ambiguous since they are also used to refer to the standard language.

The Low German dialect area lies north of a line crossing the Rhine at Benrath just south of Düsseldorf (the Benrath line) and running in a roughly east-west direction across the entire German-speaking territory, passing to the south of Berlin, and crossing the river Oder south of Frankfurt an der Oder on the Polish border. Insofar as dialect, in the German sense, can be found there at all, Berlin can be seen as an island (or perhaps peninsula) of Central German speech in Low German territory. Some German accounts include Dutch in the Low German dialect area but, although Dutch and Low German are linguistically close, sociolinguistically it is untenable that Dutch is a Low German dialect. The Low German dialects are arguably the group of German dialects that differ most markedly from the standard language. This is not surprising since the standard language historically derives chiefly from central and southern dialects. The Low German/*Niederdeutsch* dialect area is characterized by the relative weakness of the traditional dialects, popularly labeled *Plattdeutsch*; indeed, it is perhaps fair to say that the region is seen by other German speakers as a bastion of the standard language.

Serious scholarship presents a much modified view; according to Stellmacher (1997), the rural parts of the region may have levels of usage of traditional dialect as high as some parts of the Centre and South. What is true is that most urban speech in North Germany is very clearly not traditional dialect, whereas in southern areas even quite large towns may contain many speakers whose usage is close to the traditional dialect; to northerners, southern urban speakers sound like dialect speakers, whereas to southerners, northern urban speakers sound like standard speakers. However, northern urban speech is very frequently not standard in the sense that this is understood in Germany; in other words, it is generally not formal standard language.

South of Low German, Central German dialects are divided from Upper German dialects by a line

that crosses the Rhine south of Mainz, then runs northeastwards, to the south of Frankfurt am Main and to the north of Würzburg and Bamberg, running then roughly eastwards to the border with the Czech Republic. The Germanic speech of Luxembourg, formerly described as a Central German dialect/*Mitteldeutscher Dialekt* in texts produced in Germany, is considered by its speakers to represent a distinct language, *Lëtzebuergesch*/Luxembourgish (Luxembourgeois). This is sociolinguistically well justified, as Luxembourgish is used by all sections of indigenous society and has a standardized written form (for the linguistic situation in Luxembourg, see Newton 1989: 145–149).

The Germanic speech of Alsace-Lorraine in France is almost universally regarded in Germany as German dialects – the northern ones Central German, with Upper German to the south – but a common view in France (both official and popular) is that these represent a distinct Germanic language called Alsatian/*alsacien*. Sociolinguistically the situation is complex; in support of dialect status, there is no accepted single standard form of Alsatian, but then again, in support of independent status, speakers of Alsatian often do not know standard German.

In the Central German and Upper German dialect areas, the social status of dialects and other nonstandard speech becomes generally higher the farther south we travel, although throughout the territory, traditional dialects are stronger in rural than in urban areas. The strength of traditional dialects is particularly notable in German-speaking Switzerland, where these are used by all sections of society. The link between language varieties and social status is much less clear in German-speaking than in English-speaking countries. Nevertheless, the link between grammatically nonstandard forms and low socioeconomic status is fairly clear in North and Central Germany.

Phonetic and Phonological Variation

In our discussion of German pronunciation (phonetics and phonology), orthography will be used, rather than phonemic transcription, since German orthography is a reasonably good guide to pronunciation. In phonetics and phonology, the most striking difference within German is between Low German, on the one hand, and the standard language and Central and Upper German dialects, on the other. Across the entirety of the basic lexicon of the language we find plosives in Low German corresponding to fricatives or affricates (or sequences of plosive plus fricative) in the other varieties. For example, corresponding to standard German *Pfund* (pound), *Apfel* (apple), *hoffen* (hope [verb]), *zwei* (two), *Katze* (cat), *das* (the/that), *Buch* (book), (orthographic *z* and *tz* correspond to the sequence /ts/; orthographic *ch* corresponds to the velar fricative /x/ or the palatal fricative /ç/), we find Low German forms such as *Pund, Appel, hopen, twee, Kat, dat, Book*. (There is no standard orthography for Low German; forms given here are merely a guide to typical pronunciations.) The distinct Low German forms seem to be conceptualized not just as differing in pronunciation from the standard forms, but as different lexical items, in other words, as dialect vocabulary; these are not found regularly in the colloquial speech of North Germany.

This difference between Low German and standard German arises from the operation of the second or High German sound shift in the Old High German dialects (from which standard German is mainly derived) towards the end of the first millennium A.D. The difference, which can be a severe impediment to comprehension, is of the kind frequently found between distinct but related languages; one might think of the contrast between words such as *cent* and *chateau* in French, with initial /s/ and /ʃ/ respectively, and *cento* and *castello* in Italian, with /tʃ/ and /k/ respectively. Partly because of the low comprehensibility between standard German and Low German, it is often thought of as a distinct language and, up until the 17th century [before modern standard (High) German came to be accepted as the prestige variety in the territory], a distinct process of standardization was under way for Low German. Low German is today recognized as a regional minority language, not simply as dialects of German (see Stellmacher, 1997).

The most common difference in consonants between Central and Upper German dialects, on the one hand, and the standard language, on the other, can be discussed under the heading of 'lenition.' In the dialects in question, voiceless plosives can be seen as having been 'softened' to make them approach voiced plosives in sound (though it is not at all clear, historically, that anything quite like this happened), with the two series even becoming identical. The resultant sounds are generally lenis, i.e., soft, like the voiced plosives of standard German (and of standard English) but without vocal chord vibration, in this resembling the voiceless plosives of standard German (and of standard English). These resultant sounds are spelled, in popularly impressionistic dialect orthography, with the symbols normally used for voiced plosives, i.e., *b, d*, and *g*. In some dialects, for example in much of East Central German, the distinction between voiced and voiceless plosives is largely absent, so that a word pair *Karten/Garten* may be homophones. In other dialects the distinction may be present, but the voiced and voiceless sounds may have a distribution different from that in the standard language; in some dialects the voiceless sounds are

found more commonly in words of relatively recent foreign origin, with the voiced (or lenis voiceless) sounds elsewhere – for example, in Alemannic dialects for standard German *dir* (you, familiar, singular), *Tier* (animal), and *Theater* (with an initial *t* sound) (theatre), we may find *dir*, and *Dier,* but *Theater* (again with an initial *t* sound). Lenition is found in most of Central German – apart from some western and central northern areas – and in the northern part of Upper German. As well as being a feature of traditional dialect, lenition phenomena are usually also found (at least to some degree) in colloquial speech in the regions in question.

Except where lenition phenomena occur, Central and Upper German dialects are generally somewhat closer to the standard language in consonant phonology than are Low German dialects. However, in particular phonetic environments or in certain individual words, forms resembling the Low German forms are found in Central German dialects. For example, in much of western Central German, *dat* (that, the) and *wat* (what) correspond to the standard German (and Upper German) *das* and *was*. Throughout Central German, *p* corresponds to standard German *pf* both medially and finally in words, so *Appel* is found where standard German (and Upper German) have forms like *Apfel*. West Central German, also has *p,* which corresponds to the initial *pf* in standard German words, for example, having *Pund* for the standard German *Pfund*. Interestingly enough, forms like *dat, wat, Appel,* and *Pund* are found in Central German colloquial nonstandard speech as well as in traditional dialect.

We noted above the many instances where Low German dialects have plosives, whereas Central and Upper German dialects and the standard language have fricatives or affricates. However, in the case of the velar obstruents in a word's initial position, most forms of German have only plosives, with Low German *Kat* and standard German *Katze* agreeing in initial consonant. In contrast, southern Upper German dialects have affricates or fricatives in the initial position of such words: for example, a common Swiss equivalent of *Katze* is *Chatz*, where orthographic *Ch-* represents a velar affricate /kx/. It is difficult to say if this Upper German feature is found in colloquial speech, since this region's everyday language already uses overwhelmingly traditional dialect anyway, or varieties very close to this.

A further feature widespread in Central and Upper German dialects is an absence of the front rounded vowels, corresponding to orthographic <ü> and <ö>, found in standard German and in Low German; front unrounded vowels are found instead. The following pairs of distinct words in standard German could in the relevant varieties be homophones: (1) *vier* (four) and *für* (for) and *Sehne* (tendon) and *Söhne* (sons). (In reality, the situation is usually more complex than this; the examples are intended only as a guide to what can happen.) The absence of front rounded vowels is a feature of both traditional dialect and colloquial nonstandard language.

Varieties of German have many other differences in vowel sounds. One important one clearly separates dialect, on the one hand, from standard and colloquial speech, on the other. Most Low German dialects, but also many others, particularly in the Southwest (including Switzerland) have monophthongs /i:/ and /u:/ where the standard language, and other varieties, have diphthongs. Examples are southwestern *Ziet* and *Hus* for standard *Zeit* and *Haus*.

In some West Central German dialects, and in Luxembourgish, contrasts between words are effected not only by differences between vowels and consonants, but also by tonal differences, a phenomenon common in the languages of the world, but rare in Europe, where the best-known examples are found in Norwegian and Swedish. Though neither widespread nor well known to German-speakers as a whole, this feature underlines the extraordinary diversity of German dialects. (For discussion of tonal contrasts see Newton, 1989: 153–156, where he terms the phenomenon 'correption.')

Syntactic and Semantic Variation

Traditional German dialects also clearly differ from standard German in grammatical structure, most notably in the noun phrase and the verb phrase. For example, where standard German has four morphologically distinct cases in the noun phrase, Low German has only two, which we may term nominative and oblique. In all continental West Germanic speech, apart from formal standard German, morphologically distinct genitive cases are now rare; however, Losses of other case distinctions are quite highly stigmatized and uncommon in colloquial language.

Differences between varieties of German in the noun phrase represent quite striking typological differences between more and less highly inflected types of language, differences that elsewhere might be associated with the distinction between one language and another.

In the verb phrase, distinctions found in the formal standard language may be absent in other varieties or may be conveyed in different ways. Most notably, a semantic distinction between the two past tenses, perfect and preterite, the latter also known as simple past or imperfect, is probably now in doubt in almost all varieties of German in most contexts; for example, *ich sah ihn* (preterite) and *ich habe ihn gesehen*

(perfect) (both translating as either 'I saw him' or 'I have seen him') are generally entirely synonymous, but with the former being stylistically marked as more formal. In North and Central German speech, in both Low German and Central German dialects, and in colloquial language, preterite forms are found, but the only common ones are those of modal and other auxiliary verbs and a few others, for example: *war, hatte, musste, mochte, sollte, wollte, konnte, durfte, wurde, sagte, meinte*. In the regions in question, and for these particular verbs, those may actually be the most common past tense forms; for almost all other verbs, perfect forms are much more common, with preterite forms generally being formal or highly formal in register. Given that the preterite and perfect forms are generally synonymous, these labels are misleading; it would make more sense to talk, for example, about simple and periphrastic past forms. I continue, however, to use the terms preterite and perfect, since they are so well established.

In the South German speech of Germany, Switzerland, and Austria, particularly in Upper German dialects, preterite forms of any verbs are entirely absent, being replaced by perfect forms. As preterites are not found in everyday speech in these regions, they are regarded as highly formal, and children have to be taught these in school.

The presence in some varieties of German of a tense/aspect distinction, which is absent in others, again represents the kind of radical differences that elsewhere could correlate with the distinction between one language and another.

Dialects and colloquial speech also differ from formal standard language in the occurrence of subjunctive forms. The formal standard language has two sets of subjunctive forms, first and second subjunctive. Each of these has two tenses, which I will term as 'nonpast' and 'past.' For example, from the verbs *kaufen* (buy) and *fahren* (travel) first subjunctive nonpast forms are *er kaufe* and *er fahre* (contrasting with indicative or 'normal' forms of these verbs, *er kauft, er fährt*), and 'past' forms are *er habe gekauft* and *er sei gefahren* (contrasting with indicative forms of these verbs, *er hat gekauft, er ist gefahren*). These first subjunctive forms are usually termed 'present subjunctive' and 'perfect subjunctive,' respectively.

Second subjunctive forms of these verbs are (1) *er kaufte* and *er führe* (nonpast) and (2) *er hätte gekauft* and *er wäre gefahren* (past). These second subjunctive forms are usually termed 'imperfect subjunctive' and 'pluperfect subjunctive,' respectively, but such terms are highly misleading because they are not imperfect or pluperfect in tense/aspect reference.

In the formal standard language, first subjunctives are used in reported speech, particularly when speakers or, much more frequently, writers wish to distance themselves from the information – in other words, to indicate that the information may not necessarily be true (without calling the user of the original words a liar); the first subjunctive is hence very popular with journalists. The first subjunctive is clearly formal, and it is not used in colloquial speech or in dialect, being replaced by the indicative, or by the second subjunctive where the distancing effect is clearly desired.

Many second subjunctive forms are also formal, indeed, highly formal or rare or archaic. In the case of nonpast forms like *kaufte*, they are avoided because they are identical to indicatives of the same verbs. In fact, the only common subjunctive forms in German are past tenses like *er hätte gekauft* and *er wäre gefahren* and the nonpast forms of modal and other auxiliary verbs: *wäre, hätte, müsste, möchte, sollte, wollte, könnte, dürfte, würde* – with dialect and colloquial nonstandard *söllte* and *wöllte* often replacing *sollte* and *wollte*. Nonpast subjunctives of other verbs are formed on the following pattern: *würde kaufen, würde fahren*. These common subjunctive forms are indeed very common, being used to express hypotheses and, along with modal particles and particular lexical items, are the main way to express all types of modality such as supposition, doubt, and volition; the other major function is in conveying politeness. The use of subjunctives is a characteristic of all types of German, but the range of forms is a major indicator of the dividing line between the formal standard and other varieties.

This difference in the range of forms is again of quite a radical kind, which elsewhere would be associated with differences between languages.

Causes of Variation

In discussing the variation in German, it is tempting to assume that colloquial language represents simply a kind of compromise between the standard language and traditional dialects and, hence, that description of the dialects can form the basis of a full account of variation. However, it is clear from the above account that such an assumption would lead to considerable oversimplification (see Barbour and Stevenson 1998: 156–157, 1990: 146–147). There is strong evidence of cases where developments in the colloquial language are independent of phenomena in traditional dialect; for example the uvular 'r' sound [R], originally not considered part of formal standard, is now gaining ground everywhere in Germany and Austria, even in regions where it is not found in traditional dialect. A loss of the distinction between /ç/ and /ʃ/, as found at the ends of the standard German words *ich*

and *Fisch*, is spreading in Central German colloquial speech, even in areas where the distinction is maintained in traditional dialect.

The idea of straightforward contact or interference phenomena used to be popular in discussions of varieties that arise from language contact. Such a variety, guest worker German (*Gastarbeiterdeutsch*), the German of immigrant workers and their families, was found in fact not to result in any simple way from contact between German and the immigrant workers' first language (see Barbour and Stevenson 1998: 211–223, 1990: 192–203). *Gastarbeiterdeutsch* is characterized (1) by lack of verbal inflections, with forms like infinitives being used throughout, while the languages in contact generally have verbal inflections; (2) by verbal-final word order, found only in Turkish (and to a limited extent in German itself) among the contact languages; and (3) by absence of gender distinctions, this being only a characteristic of Turkish. It must be stressed that these phenomena are found in the German of speakers of all of the contact languages, including those who have no contact with Turkish speakers. Among second and third generation immigrants, guest worker German is now of very limited importance. Their speech is characterized by code switching between German and another language, a phenomenon that goes beyond our topic of variation in German.

Lexical Variation

The differences within German discussed so far tend to separate the formal standard language from other varieties, while also having important regional dimensions. When considering lexical differences, the regional dimension is all-important. In lexical differences, however, the pattern is extremely complex, and a full discussion would far exceed the limits of this article; I shall therefore make only a few salient points. (For further information see Eichhoff (1987, 1988); and König 1978). As in other facets of the language, German is surprisingly diverse; there are differences between lexical items of related meaning that in other language groups may be cognate across a number of different languages. For example, different varieties of German have different names for days of the week, which, in contrast, are clearly cognate across the entire Western Romance group of languages. *Erchtag* (Bavarian-Austrian dialects), *Ziestag* (some other southern dialects, including Swiss dialects), and *Dienstag* (other regions and the standard language) all refer to Tuesday; *Sonnabend* (standard language and other varieties – North), *Samstag* (standard language and other varieties – South), and *Saterdag* (some northwestern dialects), all refer to Saturday. Southwestern dialects even have a regional word for father, *Atti*, contrasting with the general *Vater/Vader*, the latter having cognates across the entire, vast Indo-European language family.

There are even regional varieties of pronouns, a phenomenon that causes serious comprehension difficulties, for example, forms like *he, him* (English 'he,' 'him,' 'it') in Low German and some Central German dialects where the standard language and southern dialects have forms such as *er, ihn, ihm*. Many Bavarian dialects have forms like *ös/es, enk* while the standard language and other dialects have forms such as *ihr, euch* ('you' – plural familiar forms). These pronouns' variants are restricted to traditional dialect (although there are traces of the Bavarian *ös/es* forms in colloquial language), but a further regional variant, *mir*, where the standard has *wir* (we), is extremely widespread in both colloquial language and dialect in the South.

In looking at the variation in German, it is important to remember that the language is a major factor in defining German national identity. This was particularly so before the political unification of Germany in 1871 and during the years of the division in Germany between 1949 and 1990. In the German-speaking area before 1871, the immensely diverse dialects were unable to function as symbols of national unity, so this role fell to the standard language. Perhaps this is why many German speakers are anxious about diversity in the standard language – there is a feeling it should be the same everywhere. In paradoxical contrast, dialect diversity, which is prized as the symbol of local or regional identity, is also extremely important to German speakers, probably because of the late achievement of national political unity. Given its number of users, standard German is inevitably diverse, particularly in the lexicon, but there is often a kind of grassroots feeling that this should not be so. The major lexical divide is a North-South one, but with precise boundaries between northern and southern forms lying in different places for different items; common examples would be southern *Ross* and *Bursche* compared with northern *Pferd* and *Junge* ('horse' and 'boy') and the variants for 'Saturday' already given. A particularly salient difference is that between northern *Guten Tag* and southern *Grüss Gott* ('good day, hello'). The so-called diminutive suffix, which actually has a wide variety of pragmatic as well as semantic functions, also divides North from South, with northern and central *-chen*, southeastern *-erl* or *-el*, and southwestern *-le* or *-li*. The formal standard language has *-chen* and *-lein*, so the southern forms given here may be seen as colloquial. Diminutives are very much more common in the South than the North.

Austrian German

One of the most widely discussed lexical divides in standard German is that between Austrian and German varieties. Items concerned are, of course, words referring to the different political and administrative systems in the two states, such as Austrian *Matura,* contrasting with German *Abitur* (school-leaving examination), but also a number of words for foodstuffs, such as Austrian *Schlagobers, Marille* contrasting with German *Schlagsahne, Aprikose* (whipped cream, apricot). It must be stressed that here we are concerned with variants that occur in all Austrian varieties of German – including the formal standard language – not just in traditional dialect. Not surprisingly, Austrians tend to regard the differences between Austrian German and the German of Germany as particularly significant, failing to realize that they are a special case of the more general North-South divide in German.

Austrian attitudes towards Austrian varieties are complex; on the one hand, there is an identification and pride in Austrian German, demonstrated by Austria's insistence that Austrian food terminology be used in the EU's dealings with Austria. On the other hand, there is a strange kind of reluctant acceptance that varieties of German from Germany may be more correct – Austrians may even be heard referring to their standard language as 'a dialect.' This stems partly from 1871 when the greater part of the German-speaking area was divided between two states; one retained its traditional title of Austria, while the other, the large new state dominated by Prussia (with its capital in Berlin) adopted the title of the German Empire, popularly known as Germany/*Deutschland*. A view arose, partly unspoken, that the German Empire was the repository of authentic Germanness and the authentic German language, particularly because it was the larger state and largely German-speaking, in contrast to the multilingual Austro-Hungarian state. This view was bolstered by the northern varieties of standard German that already were popularly seen as 'more correct.' For a comprehensive account of the differences between the major national and regional varieties of German and of their social and political correlates, see Ammon (1995).

Swiss German

The 'ownership' of standard German by the German state has produced the reaction in contemporary Switzerland that all standard German is in some sense 'foreign' to Switzerland. There is a Swiss standard German particularly characterized – like Austrian standard German (and the standard German of Germany) – by distinctive lexicon and recognized as Swiss by Germans and Austrians, but the German-speaking Swiss are increasingly using it only to communicate with non-Swiss German-speakers or in the most formal contexts. They are using Swiss dialects, known as Swiss German/*Schweizerdeutsch/ Schwyzertüütsch,* in almost all other spoken communication. This state of affairs could suggest that the Swiss dialects now represent a separate language from German, but this is not quite the case; Swiss German does not have any generally accepted standard variety and it is relatively rarely used in writing. Some of the most salient distinctive lexicon of Swiss German consists of items of French origin, such as *Chauffeur* ('driver'), or items referring to specifically Swiss social and political institutions, like *Bundesrat* (Swiss Federal government – not to be confused with the *Bundesrat* in Germany, the upper house of parliament).

East and West German

During the 40-year division of Germany, particularly because contact between the citizens of the two states was restricted, all varieties of the language, including standard varieties, diverged in the Federal Republic (west) and the German Democratic Republic (GDR) (east). Given the important role of language in the German national identity, this divergence became a highly charged political issue, with attitudes ranging from outrage on the part of some conservative West Germans at perceived Communist efforts to destroy national unity, to the vision in some GDR circles of language renewal paralleling social renewal in the East. A balanced view would perhaps see changes in both East and West reflecting change and divergence on both sides. The most obvious differences did indeed reflect different experiences of life in the two republics with, for example, an entire political and social vocabulary for East German institutions, such as *Volkskammer* (GDR Parliament), *Polytechnische Oberschule* (comprehensive School), and *Objekt* (building) but also some perhaps unexpected everyday items, such as *Kaffee komplett* (coffee with milk and sugar).

As the unification of 1990 was in effect an absorption of the population and territory of the GDR into the Federal Republic, it might have been expected that differences in language would steadily be eliminated. Many GDR-specific terms, particularly political and economic terms, have indeed disappeared or are obsolescent, but there have been some surprising survivals. Many of these represent salient GDR terms, which are used to stress continuing East German

identity on the part of the many for whom unification has been more or less a disappointment; an example here would be *Broiler*, for Western *Brathähnchen* (roast chicken). On occasion, East Germans seem simply unaware that they are using GDR-specific language; I have heard *Objekt* (public building) and *Kaffee komplett* (coffee with milk and sugar) used unselfconsciously in this way. For a comprehensive account of the linguistic differences between East and West – past and present – set against the political background, see Stevenson (2003).

Conclusion

As discussed, there is public concern about variability in the standard language, and this is currently perceived as an increasing problem. Of particular current concern is the perceived divide between 'traditional' or 'authentic' German and the new variety 'corrupted' by English influence. As I have argued elsewhere, though perhaps partly justified in certain respects, this concern is plagued by misconceptions about language change and comprehensibility (see Barbour, 2001).

The new concern about variability in the standard language may be arising not from any change in the substance of the language, but from increasing use, in formal contexts, of words and constructions previously thought of as informal. In linguistic terms, a new standard language may be arising, creating from the formal standard (*Standardsprache*) and the colloquial standard (varieties of *Umgangssprache*) a new type of multi-register standard variety such as that found in English. Concern about variability in the standard language is attested to in the papers in Eichinger (2005).

It is often said that German dialects are being used less, thus making the language more uniform, but increasing variability in the standard language may be compensating for this, ensuring that German continues to show high salient patterns of variation.

Variation in Native Languages of North America

S Trechter, California State University, Chico, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

The concept of variation has framed discussions of Native North American linguistics from its beginnings. In his introduction to the *International Journal of American Linguistics* in 1917, Franz Boas summarized what direction such a journal should take toward further understanding of the complexities within and the relationships between American indigenous languages. His outline and exhortations serve to broadly define the scope of linguistic variation for indigenous language study: for the purposes of dialect and language identification, linguists should extend their examination beyond lexical cognates and sound correspondences to an analysis of morphological variation existing in polysynthetic languages. Recognizing linguistic change induced by daily contact with speakers of European languages, comparison across generations would be vital. Particular attention should be paid to examining the variation that occurs between different genres of speech from conversation to folktales to ritual performance in order to capture lexical variety as well as literary convention. The linguist should be aware of not only individual variation such as that associated with a poet, but also the types of variation that may be conventionalized across particular groups of people. Such a broad focus is more akin to ethnography of speaking than mere study of variation, and this focus is integral to research in Native North American languages.

Much indigenous language variation is overtly recognized as a genre or identity marker by community members, rather than the minute, subconscious indicators of gender, class, and ethnicity described in the study of more widely spoken languages. As a personal characteristic of everyday speech, variation indicates a particular position taken by a speaker with respect to his interlocutors in a context. Some indicators of a speaker's identity may be less contextually malleable than others – such as regional background. Other variations that occur may indicate personal characteristics of the speaker or addressee (gender, age, physical handicaps) or intentional affect. Interestingly, though such 'exotic' forms have often been attributed to North American languages, they are not typically categorical. They are often associated with specific genres of speech or circumstances and give rise to a variety of expressive nuances. Finally, some variation is almost completely determined by genre, such as ritualistic or shaman's language, announcements, prayers, and folktales, rather than the identity of the speaker. However, speakers' abilities to engage in certain kinds of formalistic language may also indicate something about their overall position in society and certainly their position of authority in a ritualistic context. Despite language attrition, which affects all kinds of language variation, Native North America is rich in linguistic variety and the variation exhibited.

Regional Dialects and Mutual Intelligibility

Given the large number of languages, approximately 300 north of Mexico, determining the difference between dialects and languages and their similarities is a process of constant revision. Many languages such as Yuchi, Zuni, or Takelma are apparent isolates. Others, however, are parts of extensive dialect continua, such as Ojibwe (Ojibwa) (Algonquian), Western Apache (Athabaskan), Straits Salish (Salish), or Dakota (Siouan). The variation that exists from one community dialect to the next can be an important marker of ethnic identity, and where this ethnic distinction is particularly emphasized, some speakers may be willing to sacrifice mutual intelligibility with other dialects to maintain their distinctiveness. In such circumstances, native speakers are quite willing to criticize each other for mixing forms from another dialect or language, or for innovating too much. The languages of the pueblos in the southwest are particularly famous for such emphasis on linguistic purity. The Arizona Tewa (Kiowa-Tanoan) strongly proscribe language mixing in *kiva* speech and overtly maintain that Tewa is 'pure' despite multilingualism and continual contact with the Hopi (Uto-Aztecan) for the past 300 years. Indeed, there are almost no adoptions of vocabulary from Hopi into Tewa, but there appears to be considerable influence from Hopi phonology and grammar. Likewise, the White Mountain Apache claim their linguistic separation along a dialect continuum from Navajo to other Western Apache dialects from Tonto/Camp Verde-White Mountain-San Carlos through overt comments about mixing:

> That's the way that they talk at San Carlos . . . that's not our word, that's a Navajo word . . . when he goes to Camp Verde he comes back and says things like they say things. That's wrong, we don't say them like that over here. He needs to stay in one place. (Greenfield, 1999: 375)

In other dialect continua, such as among the Creek (Muskogee) (Muskogean) of the southeastern United States, Dakota (Siouan) of the Great Plains of the United States and Canada, or the Ojibwe (Algonquian) in the Canadian regions of the Great Lakes, strong

Table 1 Sioux dialects

Teton	lak^{h}ota	-la	tʃistila	gla	gnayã
Santee	dak^{h}ota	-da, -dã	tʃistina	hda	hnayã
Sisseton	dak^{h}ota	-na	tʃistina	hda	hnayã
Yankton	dak^{h}ota	-na	tʃistʃina	kda	knayã
Yanktonai	dak^{h}ota	-na	tʃistʃina	gda	knayã
Assiniboine	nak^{h}ota	-na	tʃusina	kna	knayã
Stoney	nak^{h}oda	-n	tʃusin	hna	hnã
	'Indian'	'diminutive'	'little'	'go home'	'cheat'

(Adapted from Parks and DeMallie, 1992.)

phonological or lexical shibboleths are noted or occasionally mocked when a speaker moves from one community to another, but there is more tolerance for mixing. Attitudes towards archaism, purity, mixing, and new languages are as varied as the dialects themselves.

Assessing Variation

Native speaker judgments concerning dialect mixing are of some use in establishing what should be counted as variation between dialects; yet native speakers tend to focus on a limited number of shibboleths as markers of linguistic or social identity. The fast and dirty nature of some early linguistic studies in Native North America has also promulgated certain misconceptions concerning dialect differentiation, and linguists are continuing their efforts to document basic regional dialect differences. Regular differences in vocabulary and pronunciation are still the starting points for this effort.

Sound and Lexicon

The dialects of Sioux (Dakota), which are spoken in the Great Plains of the United States and Canada, form a well-established dialect continuum. This continuum has been mistakenly broken into three distinct dialects based on a regular pronunciation difference that is apparent in the word for 'Indian': *lak^{h}ota* – Teton, *dak^{h}ota* – Santee, Sisseton, *nak^{h}ota* – Yankton-Yanktonai, Assiniboine, and Stoney. Based on such linguistic division, natives have sometimes categorized each other along the same lines. A cursory examination, however, reveals this categorization to be inaccurate. Parks and DeMallie's report of their recent dialect survey revealed considerably more phonological variation for /l, d, n/ among the dialects, such as in the diminutive suffix and the word for 'little'(see Table 1). A better phonological diagnostic is in fact the pronunciation of the first consonant in a cluster when the second is a sonorant, as in *hnayã* 'cheat.' They concluded that phonologically Yankton and Yanktonai (Minnesota, Nebraska, Saskatchewan), rather than being n-dialects, are closer to Santee-Sisseton (Nebraska, Minnesota, North Dakota, Manitoba, Saskatchewan) than to Assiniboine (Saskatchewan, Montana). Stoney (Alberta), because of its vast difference phonologically and lexically and the influence of Cree (Algonquian) grammar, is a separate language from the others in the continuum.

Grammar

Although traditional phonological comparisons of lexicon and morphological affixes are indispensable for establishing dialect differences, Valentine has recently asserted that the incorporating nature of many indigenous languages offers a unique opportunity to trace variation within a dialect continuum and better understand similarities. The eight dialects of Ojibwe (Algonquian), spoken from Quebec to Saskatchewan, demonstrate considerable lexical variation because of the complex structure of their incorporating verbs. Verbs contain at least three basic slots: initial, medial, and final. For one verb, both the structural components filling these slots and lexical variation within the slots may occur. Among the Ontario dialects, the animate intransitive body part verb *ozhaawashkoshkiinzhigwe* 'have blue eyes' (Lake Nipigon) differs considerably although the initial, 'blue/green,' is the same (see Table 2). Tracing such complexity of variation is a fruitful direction for languages that become increasingly better documented.

Intergenerational Variation and New Language

Numerous linguists have commented on the difficulty of creating adequate descriptive grammars and dictionaries for languages, partly due to the amount of variation that exists between regional dialects and due to variable use, but also because of intergenerational shift. Such complexity is magnified in contact language situations, where intergenerational language attrition can be quite dramatic. Linguists of Boas's generation encouraged researchers to work with older, more expert speakers in order to have good comparative data, but as language attrition, maintenance, and revitalization have become part of the accepted reality of most linguists working in the

(Adapted from Valentine, 2002: 91.)

Americas, focus has shifted to better understand variation caused by language attrition. It is now a type of variation not only associated with language death, but as vital to accounting for language revitalization.

In a comparatively early study, Hill traced the grammatical reductions in two southern California languages, Luiseño and Cupeño (Uto-Aztecan), demonstrating that in a 40-year period, speakers' grammar became increasingly more predictable as they displayed less subordination and came to favor shorter sentences. Cook, however, has observed the double nature of variation induced by language attrition: it tends to reduce the phonemic inventory, grammar, and stylistic options for individual speakers, but simultaneously the language on the whole exhibits more variation because the idiolects of semispeakers display a range of such reductions. Instead of speakers 'reducing' linguistic variation, they are in fact caught at various stages of incomplete language acquisition. Cook maintained that the younger speakers of Sarcee (Sarsi) (Athabaskan) and Chipewyan (Algonquian) in western and northern Canada are speakers of 'dying' languages and therefore have a wide variety of innovations, archaisms, and phonological idiosyncrasies.

There is a fine ideological line between the speakers of a 'dying' language and those of a 'new' or 'revitalized' language although they may demonstrate the same phonological and structural reductions in addition to the variation typical of nonnative speakers. Recently, in a standard study of the regional dialects of Straits Salish (Salishan) spoken north and west of Puget Sound in Washington State and British Columbia, Montler grouped the dialects into two separate languages based on their nonmutual intelligibility: Klallam with three dialects and Northern Straits – a continuum of Sooke, Songish, Saanich, Lummi, Samish, and Semiahmoo. This classification is largely based on differences and similarities in lexical items, phonology, person marking and reduplication, demonstratives, and second-position enclitics. However, in Northern Straits, intergenerational variation within one family is as great as any variation from one dialect to the other. For instance, younger Saanich speakers tend toward periphrasis to express diminutives rather than reduplicating by adding /-C_1ə-/ after the first stressed syllable: */məmím'ən sŋénət/* 'small stone' instead of */sŋəŋéʔnət/*. When younger speakers do use reduplication, they display the greater individual variation described by Cook by either regularizing (as seen below) or exaggerating through additions of too many syllables:

Younger:	*ʔíləqsən*	'point of land'	*ʔəʔíʔləqsən*	'small point of land'
Older:	*ʔíləqsən*	'point of land'	*ʔəʔəléqsən*	'small point of land'

The greatest amount of innovation is seen, however, among new speakers of revitalized languages – New Lummi, New Saanich, and New Klallam (Clallam) – in which some speakers are very fluent. These varieties are growing through language revitalization efforts, and display even more of a tendency to periphrastic structures as lexical suffixes are eliminated and verb paradigms are leveled. Phonologically, there is extreme change with the loss of glottalization on sonorants and some obstruents, vowel epenthesis in some clusters, and a shift toward more English-like sounds: /q/ becoming /k/ and /tl̥'/ becoming /k'l/ or /kl/. These are not symptoms of language death, but endemic of revitalization efforts as monolingual English speakers acquire an ancestral language.

Personal Indicators in Speech

It is somewhat common throughout the world's languages to modify the speech of direct address to demonstrate respect by modifying vocabulary, or using morphological plurals or passives to create a 'distancing' effect. Similar modifications are made in addressing strangers or in-laws in several indigenous languages such as those of northern California and Navajo (Athabaskan). Such accommodations in the presence of addressees serve to indirectly index their respected position in a speech event. Some indigenous languages of the Americas extend such indexicals to allude to specific or personal information of speech participants or when describing others. This is accomplished through a variety of manipulations of sound symbolism, lexicon, morphology, and phonology. The kinds of information expressed include specific

physical characteristics or types of speech associated with certain characters in folktales, affection displayed toward younger or cute addressees, and the gender of the speaker and/or addressee.

Folk Characters and Abnormalities

Characters in folktales such as Coyote, Grizzly Bear, Mountain Lion, or Rabbit often have specific speech styles such as lisps, consonant substitutions, and frontings, or prefixing of certain sounds (see 'Special language' in Mithun, 1999 for a detailed overview). In Takelma (Oregon isolate), Dell Hymes argued such features are not used across the board but expressively to associate specific contextual qualities with the folk characters. Although Grizzly Bear speech in Takelma is well-known for /ɬ/-prefixing, this is only done to indicate coarseness, stupidity, disdain, and distance. Likewise, indicators of physical or personality characteristics of people are not obligatory. Nootka (Wakashan/Vancouver Island), Quileut (Quileute) (Chimakuan/Washington), and purportedly a number of other northern Pacific coast languages oftentimes express negative personal characteristics such as greed, shortness, fatness, lameness, eye problems, or left-handedness through the addition of a morpheme and what Sapir calls "consonantal play." For instance, an augmentative suffix /*-aq*/ is used for fat people: /*haʔokwiɬhak*/ 'did you eat?' versus /*haʔokwaqiɬhak*/ 'did you eat, fatty?' The diminutive suffix /*-ʔis*/ is added to forms referring to crossed or squint eyes, and all sibilants are converted to corresponding lateral forms: /*q^{w}ísmah*/ 'he does so' versus /*q^{w}íɬ-ʔiɬ-mah*/ 'he does so, weak eyes.' Similar 'sore eye' speech without the diminutive is used to represent the folktale characters Deer and Mink.

Caretaker Language and Baby Talk

Similarly, caretaker language and baby talk is present in most languages of the northwest coast such as in the consonant reductions and the addition of diminutive /*-ʔis*/ in Nootka. Many, though not all, languages of North America have some modifications to indicate affectionate speech to young children. Such talk is characterized by varying degrees of modification of adult forms, such as morphological diminutives and reduplication, lexical substitutions, and phonological substitutions. The latter may involve a phonological shift such as palatalization of stop consonants, e.g. /t/ becomes /tʃ/ to indicate affection. Through a sort of diminutive sound symbolism as in Omaha-Ponca, grandmother language indicates affection, cuteness, or a minimized threat of a potential danger.

In other instances, there is a reduced phonological inventory because speakers perceive it to be easier for children. Cocopa, an Arizona Yuman language, has quite complex caretaker language with at least seven different phonological rules that adult women apply to varying extents when addressing children and adolescent girls. Consonants are reduced from the adult inventory of 23 to 12 largely through elimination of secondary articulations and place. For instance, /k, k^{w}, q, q^{w}/ become /k/, and /l, l^{y}, r/ become /l/. Alternatively, adults may palatalize all dental, alveolar, and palatal consonants. Next, the consonant before the root syllable is replaced with a /v/-sound although it is not a member of the adult Cocopa inventory. Consonants and sometimes vowels that are not part of the root get dropped; an /s-/suffix is sometimes added to the end of the word; nonroot long vowels are shortened, and a diminutive /n-/prefix is added before the first consonant of the root. Men also produce the diminutive form. These changes and their variable applications create words in baby talk that can be quite complex for children to acquire in addition to their acquisition of adultlike language:

Adult speech	Baby talk	
/*k^{w}an^{y}uk*/	/*kanvúk*/	'baby'
/*lu:p mu:k^{w}i: kmyu*/	/*lu:p unvi:s yu*/	'what will you buy'
/*umits wa:ya:ts*/	/*unvít anya:t*/	'she goes around crying'

Gender

Gender indexicals are typically phonological, morphological, or lexical variants used to indicate the gender of the speaker, the addressee, or both simultaneously. These continue to receive descriptive attention in Native North America, as linguists re-examine previously gathered data and find new examples. Despite early reports to the contrary, such as Haas's article 'Men's and women's speech in Koasati,' the use of such indicators has rarely been found to be categorical. However, recent language attrition and the commensurate reduction of stylistic variation may in some circumstances have caused a greater regularity of use than was previously apparent.

Phonological Indicators Phonological gender differences have been proposed for a number of languages and exist in the length of forms, degree of nasalization, and in consonant substitution. There appears to be little crosscultural regularity in North America concerning which pronunciations will be more indicative of men than women. Haas first proposed that several Muskogean languages, specifically Koasati, indicated the male sex of the speaker, by pronunciation differences such as a final /-s/ in men's forms: /*lakawtakkõ*/ (women) versus /*lakawtakkós*/ (men) 'I'm not lifting it.' Using Haas's original field notes, historical records, comparative data, and his current fieldwork, Kimball argued that the phonological difference Haas analyzed for Koasati and proposed for related languages

was actually a choice in whether to use /-s/ (currently pronounced [ʃ]) 'sentence-final narrative particle' to supplant phrase-terminal nasalization. He also noted that this feature was due less to a speaker's gender than to his or her authority in the society as both sexes used the form. Yana (northern California) men's public speaking to both men and women was originally described by Sapir as male-to-male speech. Because of the additional syllable, 'men's forms' are lengthier, more archaic, and evocative of speech associated with elevated ritual language and indirectly with gender.

Man to man	Other	
/ʔau-ʔnidʒa	/ʔau-ʔitʃ^{h}/	'my fire'
/ʔi-na/	/ʔi/	'tree, stick'
/p^{h}adi/	/p^{h}at^{h}/	'place'

Likewise, in ritual Laguna (Keres) *kiva* speech associated with older men, regular vowel lengthening occurs in 10 'cue' words indicating the emotional stance of the speaker toward a proposition.

Female	Male	
/amú'u/	/amúu'u/	'love, pity'
/ayá'a/	/ayáa'a/	'discomfort'
/imí'i/	/imíi'i/	'fear/shy'

Several languages display slightly more nasalized forms for speech attributed by native speakers to women. In the early part of the 20th century, Inuktitut (Eskimo-Aleut) women on Baffin Island were observed to substitute nasals /m, n, ŋ, N/ for final voiceless stops /p, t, k, q/. Yet men also had variable nasal and nonnasal pronunciations. Among the Lakhota (Lakota) (Siouan) affective/illocutionary force indicators, two to three forms, such as /*-yemã*/ 'women's surprise,' are nasalized versions of men's – /*-yewã*/ 'men's surprise'. In contrast, emphatic questions in Yana required the enclitic /*-gà*/ for women and /*-nà*/ for men.

In Atsina (Gros Ventre) (Algonquian/Montana) both men and women tend to use 'women's' pronunciation' with nonnative speakers and children, but men typically front /k/ or /ky/ to /tʃ/, and women substitute /k/ or /ky/ for the more archaic /ty/. Men have apparently borrowed the fronted sound /tʃ/ from their Arapaho (Algonquian) neighbors, and younger men are currently in the process of changing /ty/ to /tʃ/ as well.

Vocabulary and Morphology Interjections, common sayings, speech act indicators, and some kinship terms vary according to the gender of the speaker or addressee in a number of languages. It is common for men and women to have different interjections for expressions of surprise, fear, or bravery in North American languages. Less common is for markers of illocutionary force to be gendered. Several Siouan languages, however, possess verbal suffixes like those listed in Mandan (Siouan) below. Mandan is the only Siouan language in which such forms are required for every sentence, and which indexes only the gender of the addressee.

Imperative	Statement	Interrogative	
/-rã/	/-ʔre/	/-ʔrã/	female addressee
/-ta/	/-ʔʃ/	/-ʔʃa/	male addressee

Other common expressions of politeness and greeting can become very salient indicators of gendered difference for native speakers. Although the forms in Table 3 do not occur in every sentence of the pueblo southwest languages, there is a strong ideology of gender-differentiated speech.

The Meanings of Gendered Forms Lists of gender differences out of context give a very minimal sense of the meaningful causes of such variation. The question of how such forms get connected to gender as they index different genres, meanings, and speech acts will lead us further to understanding the meaning of variation in specific languages (see Trechter, 1999 for such an analysis in Lakhota). Indeed, any number of linguistic forms could theoretically be linked to gender, but very few are. For example, Hill and Zepeda have recently extended the types of analysis indicative of gender differentiation to the use of the ingressive pulmonic airstream by Tohono O'odham (Uto-Aztecan/Arizona) women. The women's sucking in of breath coordinates with discourse features that index closeness and involvement in conversation, which already hold a meaningful culture value for these women. Only through contextual analysis coordinated with speakers' ideologies regarding gendered meaning are such linguistic markers better understood.

Table 3 Pueblo Southwest gendered vocabulary

Language (dialect)	*Female*	*Male*	*Meaning*
Hopi (3rd Mesa)	ʔask^{w}ali	k^{w}ak^{w}ha(-y)	thank you
Tewa (Arizona)	kuna	kunda	thank you
Tiwa	hɛrkɛm	hawə˞	thank you
Acoma	náidrá	huw'ehé	thank you
Hopi	sónwayo	lóloma	it's beautiful
Acoma	an^{y}umé:c'a	ʔanyi:c'e	it's beautiful
Tewa (Arizona)	ʔasagi	sagʔwo'	it's beautiful
Hopi		taʔa	yes
Tewa (Arizona)	hã:	hoy	yes
Tewa (Rio Grande)	hoy	hãman	yes
Acoma	hée	haí	answer to a call
Hopi	yá:sayoqu	hósqaya	be huge
Tewa (Arizona)	-ʔáyyá	-ʔóyyó	be good

(Adapted from Maring, 1975; Kroskrity, 1983: 89; Sims and Valiquette, 1989.)

Stylistic Variation

In a 1927 article, 'Literate and illiterate speech,' Bloomfield assessed Menominee (Menomini) (Algonquian) speakers in Wisconsin, rating their grammatical and lexical capabilities. He described three different ways of saying 'What are you laughing at?' – */wékiʔ wéh-ayéniyan/*, */wékiʔ aya:yó:sinama/*, */tá:niʔ wehtá:hpiyan/* – on a continuum from 'illiterate, childish, stupid' to 'normal' to 'elevated, poetic and archaizing.' The last type of language seemed to be associated with doctors and shamans, and was characterized by long vowels in unusual contexts, archaisms, and metaphorical vocabulary. 'Bad' speakers, on the other hand, anglicized their pronunciation and did not keep long and short vowels distinct. They also forgot to use the obviative (a form that distinguishes between two different third persons) and the quotative in narratives. Although Bloomfield placed most speakers under the age of 40 in the illiterate group, this was not absolute. He surmised that English interfered with a speaker's ability to control a variety of styles, but he also placed some monolingual speakers of Menominee in the illiterate group. Regrettably, Bloomfield stated that the differences in such styles of speech permeated every aspect of the lexicon and grammar to the extent that description would be impossible. It is difficult to know if Bloomfield was capturing the reduction of stylistic variation or the prejudice of a few speakers.

The Content of Style

Elevated, ceremonial, or shamanistic speech styles are recognized among many languages (Wintu, Lakota, languages of the pueblos in the southwest). On the other hand, styles of oratory in many California and west coast languages (Nootka, Tübatulabal, Patwin, Pomo, Yokuts) is reported as having been 'forced,' 'jerky,' with 'short sentences.' For an excellent comparison of such speech styles see Miller and Silver (1997). In cultures where mastery of ceremonial speech is highly emphasized, speakers must have specific abilities and be specially trained to acquire the forms. Such registers thus become less indicative of the personal or individual identity of a speaker than the genre or speech event which she or he performs.

Chafe, for instance, described three different styles of verbal performance in Seneca (Iroquoian/New York): normal conversation, preaching, and chanting. These genres differ in a number of ways: prosodically, and in the degree of formulaicity, sentence grammar, and epistemic stance. Normal conversation has greater freedom, relies less on memorized phrases, circumlocutions, or archaic language, is more fragmented because of multiple participants and lack of planning, and requires speakers as direct conveyors of original content to state the extent to which they are sure through the use of varied evidentials. Chafe demonstrated that as speakers move to preaching and chanting, their intonation contours become increasingly monotone although the sentences are lengthier and more packed with information. Preaching exhibits few evidential markers. Indeed, as the speaker becomes less individually and creatively responsible for the content of utterances, chanting contains a number of markers of certainty.

Although the definition of ritual speech requires a certain compartmentalization of the genre, there may be ideological extensions of ritual genre into everyday life to the extent that it may also affect speakers' sense of what more elevated language sounds like. From Bloomfield's description, some such linguistic ideology may have affected his definition of elevated speech in Menominee with its elongated vowels and metaphorical vocabulary. To some extent, formulaic speeches, such as the public grievance chants in Hopi (Uto-Aztecan), may have some general similarity in form to more esoteric styles. Kroskrity argued that the speech of public announcements in Arizona Tewa (Kiowa-Tanoan), although necessarily separate from the highly ritualistic *kiva* speech, follows many of the same strictures through its de-emphasis on the personality of the announcer, the formulaic structure of the announcing chant, and the unusual but predictable rising intonation throughout the three verses. To be 'valid' forms, such chants must be notifications of community events and announced by men from rooftops. More recently women have both followed the form and innovated by announcing events such as yard sales themselves.

Folktales as Verse

Since the 1970s, a number of linguistic anthropologists such as Tedlock and the Hymeses have argued that the structure, form, language, and meaning of oral, indigenous folktales are better understood if they are regarded as poetry and performance rather than prose. Tedlock, for instance, has sought to capture visually variations in loudness and prosodic features such as intonation and rhetorical lengthening through use of larger type, movement of the type up and down on the page, and the repetition of letters for lengthening. Dell Hymes saw the 'pattern numbers,' those numbers that are favored mythically by certain cultures for organizing, as important for understanding if not for reversifying previously collected folktales. One of the most famous of such analyses using this approach is Virginia Hymes's work on the 'Raven Myth' in Warm Springs Sahaptin (Tenino) (Sahaptian/Oregon). Paying special attention to the intersection of prosodic cues such as changes in voice quality

or pitch and rhetorical vowel lengthening indicative of first lines, with parallelism in the use of different grammatical particles and time words, Hymes was able to divide the narration into verses. Interestingly, a pattern of five recurred throughout. Events were repeated five times, and there were often five lines in a verse and five verses in a stanza. The pattern of three was also important. Despite the variation in some folktales and creative interpretation needed for such work, Woodbury saw such work as getting to the grammar of discourse. By understanding the similarity of forms within one oral genre, one thereby begins to see its variation from others.

Variation in Native North America has never been limited to regional dialects or the expression of cultural, ethnic, or gender identities. Linguists encountering unexpected and unfamiliar linguistic structures and expressions in North America have allowed a broad definition of variation in order to capture both the sense of complexity in the languages they described and their expressive capabilities. As today's linguists and Native peoples continue to work in a context of language attrition and potential revitalization, maintaining a broad understanding of variation in both the older forms and encountering variation in new contexts will be the challenge.

Variation in Nonnative Varieties of English

Z Bao, National University of Singapore, Singapore

© 2006 Elsevier Ltd. All rights reserved.

Native vs. Nonnative Varieties

Native and nonnative varieties of English are distinguished on the basis of the sociolinguistic environment in which they take root. Native varieties are found in North America, Australia, and New Zealand, places that saw large-scale settlement by English-speaking people. Nonnative varieties emerge in former British or American colonies in South and Southeast Asia and parts of Africa, where there has never been a sizable English-speaking settlement, and English is spoken along with the languages of the local populations. From the perspective of genetic linguistics, native varieties are the product of normal parent-to-child transmission in that both the grammar and the vocabulary are transmitted from the same parent language (Thomason and Kaufman, 1988). There is little structural difference among them. Nonnative varieties are more complicated. Though the vocabulary is largely English, the grammar exhibits significant restructuring under the influence of indigenous languages. Given their unique sociolinguistic histories, nonnative varieties are not typologically homogenous. Because of the presence of linguistic features appropriated from indigenous languages, they are often referred to as 'indigenized,' 'nativized,' or 'contact' varieties, or as 'New Englishes.'

Nonnative varieties are distinguished from English-lexified pidgins and creoles, also on sociolinguistic grounds. However, the internal variation within a nonnative variety is analogous to the post-creole continuum, ranging from basilect to acrolect. Unlike the basilectal subvarieties, the acrolect does not exhibit the effect of grammatical restructuring and serves as the local standard. It is in effect a native variety, and 'nonnative' applies to the basilectal subvarieties.

Native vs. Nonnative Speakers

'Native' is also used to describe the order of language acquisition: a 'native' language is the first language acquired by a 'native' speaker. The acquisitional status of nonnative varieties of English deserves comment. Conditioned by different postcolonial experiences, they followed separate developmental paths (Schneider, 2003). Malaysia and Singapore offer an interesting case study. In Malaysia, Malay is the national language, and English remains the language of the elite. In Singapore, the government adopts an English-centered language policy. English is the working language of government and, more importantly, the medium of instruction in schools. An English diglossia has emerged, with the nonnative variety – Singapore English – as L, and the superposed, acrolectal variety as H. Increasingly Singapore English is acquired as a first, if not the first, language (Kwan-Terry, 1991; Gupta, 1994). Given the right sociolinguistic conditions, a nonnative variety can acquire native speakers and become the mother tongue.

Variation

Variation in nonnative varieties of English is usually measured against the grammatical norm of the native variety. The focus is placed on linguistic neologisms and their possible origins. Variation can also be approached in terms of the usage patterns of linguistic variables as conditioned by context of use. But this line of enquiry is woefully lacking in the literature and is usually subsumed in the more common studies of lectal variation, conditioned by speaker proficiency. Linguistic neologisms can be found in all levels of language.

Phonetics and Phonology

Two noticeable innovations among the English consonants have to do with the dental fricatives (*thin*, *this*) and the aspirated voiceless stops (*pot*, *top*, *cop*). The dental fricatives are replaced by *t* and *d*, respectively, and aspiration of the voiceless stops is lost. These innovations illustrate two basic mechanisms of sound interference: direct substitution and change in phonological contrast. In Singapore English, there has been a further development in the treatment of the dental fricatives: they are pronounced as *t/d* in syllable-initial position, but as *f* in syllable-final position (*healthy* [-t-] vs. *health* [-f]).

Native vs. Nonnative Varieties

Native and nonnative varieties of English are distinguished on the basis of the sociolinguistic environment in which they take root. Native varieties are found in North America, Australia, and New Zealand, places that saw large-scale settlement by English-speaking people. Nonnative varieties emerge in former British or American colonies in South and Southeast Asia and parts of Africa, where there has never been a sizable English-speaking settlement, and English is spoken along with the languages of the local populations. From the perspective of genetic linguistics, native varieties are the product of normal parent-to-child transmission in that both the grammar and the vocabulary are transmitted from the same parent language (Thomason and Kaufman, 1988). There is little structural difference among them. Nonnative varieties are more complicated. Though the vocabulary is largely English, the grammar exhibits significant restructuring under the influence of indigenous languages. Given their unique sociolinguistic histories, nonnative varieties are not typologically homogenous. Because of the presence of linguistic features appropriated from indigenous languages, they are often referred to as 'indigenized,' 'nativized,' or 'contact' varieties, or as 'New Englishes.'

Nonnative varieties are distinguished from English-lexified pidgins and creoles, also on sociolinguistic grounds. However, the internal variation within a nonnative variety is analogous to the post-creole continuum, ranging from basilect to acrolect. Unlike the basilectal subvarieties, the acrolect does not exhibit the effect of grammatical restructuring and serves as the local standard. It is in effect a native variety, and 'nonnative' applies to the basilectal subvarieties.

Native vs. Nonnative Speakers

'Native' is also used to describe the order of language acquisition: a 'native' language is the first language acquired by a 'native' speaker. The acquisitional status of nonnative varieties of English deserves comment. Conditioned by different postcolonial experiences, they followed separate developmental paths (Schneider, 2003). Malaysia and Singapore offer an interesting case study. In Malaysia, Malay is the national language, and English remains the language of the elite. In Singapore, the government adopts an English-centered language policy. English is the working language of government and, more importantly, the medium of instruction in schools. An English diglossia has emerged, with the nonnative variety – Singapore English – as L, and the superposed, acrolectal variety as H. Increasingly Singapore English is acquired as a first, if not the first, language (Kwan-Terry, 1991; Gupta, 1994). Given the right sociolinguistic conditions, a nonnative variety can acquire native speakers and become the mother tongue.

Variation

Variation in nonnative varieties of English is usually measured against the grammatical norm of the native variety. The focus is placed on linguistic neologisms and their possible origins. Variation can also be approached in terms of the usage patterns of linguistic variables as conditioned by context of use. But this line of enquiry is woefully lacking in the literature and is usually subsumed in the more common studies of lectal variation, conditioned by speaker proficiency. Linguistic neologisms can be found in all levels of language.

Phonetics and Phonology

Two noticeable innovations among the English consonants have to do with the dental fricatives (*thin*, *this*) and the aspirated voiceless stops (*pot*, *top*, *cop*). The dental fricatives are replaced by *t* and *d*, respectively, and aspiration of the voiceless stops is lost. These innovations illustrate two basic mechanisms of sound interference: direct substitution and change in phonological contrast. In Singapore English, there has been a further development in the treatment of the dental fricatives: they are pronounced as *t/d* in syllable-initial position, but as *f* in syllable-final position (*healthy* [-t-] vs. *health* [-f]).

Table 1 Simplification and vowel inventory

RP			*Nonnative*		*Examples*	
iː/ɪ	uː/ʊ		i	u	*beat/bit*	*boot/put*
ɛ	ɔː/ɒ	⇒	e	o	*bet*	*caught/cot*
æ	ɑː/ʌ			a	*bat*	*cart/cut*

The change in the vowel system is more drastic. The typical vowel inventory of a nonnative variety consists of five or seven vowels. The additional two vowels in the larger inventory are traceable to the diphthongs in *bait* and *boat*. A plausible explanation is that the five-vowel inventory is due to simplification in phonological contrast. Table 1 displays the result.

The five-vowel inventory emerges when length is no longer phonemic and the high–mid–low contrast is reduced to high–low. The loss of phonological contrast may be caused by contact with indigenous languages or by internal drift.

Lexicon and Morphology

The lexicon is a depository of words and is the part of language that is the most susceptible to external influence. Lexical borrowing is commonplace. Not surprisingly, nonnative varieties borrow words from the languages in their contact environment: *dhobi* 'washer man' (from Hindi) in India, *kampong* 'village' (from Malay), and *kaypoh* 'nosy' (from Chinese [Southern Min Chinese]) in Malaysia and Singapore. It is not easy to differentiate this sort of direct borrowing from code-mixing or code-switching, which are common phenomena in multilingual communities.

New meanings may develop. In Southeast Asia, to *gostan* (< *go stern*) is to change direction; an *alphabet* is a letter (*English has 26 alphabets*), and a *parking lot* is a space in a *car park*. A more subtle change involves the lexical semantics of words. Take *win* and *admit*. In Euro 2004, Greece played Portugal and won. To report this in Singapore English, you can say *Greece won*, *Greece won the game*, or *Greece won Portugal*. The last sentence reveals the change in the lexical semantics of *win*. The same is true of *admit*, as in *Teachers admit this exhibition for free*, on a museum notice board advertising a special exhibit.

Inflection is poorly developed. This is not to say that plural marking and verb agreement are completely lacking. More commonly, they are used apparently at random and may occur in unexpected places (recorded telephone message in Singapore: *This transfer will take*s *about five seconds*). The complex verbal morphology associated with aspectual meanings suffers the same fate. However, differences in the aspect system are often due to underlying systematic differences in the way aspectual meanings are expressed.

Grammar

In the literature, grammatical description of the nonnative varieties, with the possible exception of Singapore English, is not as extensive and detailed as that for English-lexified pidgins and creoles. Nevertheless, from the available descriptions it is possible to appreciate the structural diversity within them. Topic prominence is a significant typological change that has variable structural instantiation among the extant nonnative varieties. The topic structures of Singapore English are as extensive as those in Chinese, its main substrate language. A typical example is *everything also want*, the title of a local comic strip. Here, we see Chinese influence in the fronted topic *everything*, in the adverb *also*, which reinforces the meaning of the quantifier *everything*, and in the missing subject. Related to the topic structure is the novel conditional construction in which the protasis is not introduced by *if*. In *Don't want egg, please inform first*, the protasis is interpreted as the topic that specifies the condition for the apodosis. Typologically or parametrically related syntactic properties tend to cluster in substrate transfer. Other nonnative varieties also allow missing arguments, but they do not have the same range of topic structures (Cheshire, 1991; Baumgardner 1996).

Another significant, and often substrate-driven, change concerns the aspectual system, which varies across the nonnative varieties (Platt *et al.,* 1984). In Singapore English, the perfective aspect is expressed by *already* (*I wash my hands already*), which occurs predominantly in clause-final position. Careful analysis reveals a subtle yet systematic difference between *already* and the past tense or perfect of native English. While *I wash my hands already* may be rendered as *I washed* (or *have washed*) *my hands*, *the wall white already* means that the wall is white, not that the wall was or has been white. This use of *already* is consistent with the perfective aspect of Chinese.

Register

Nonnative varieties of English do not have an accepted written form, unlike some English-lexified pidgins and creoles, such as Tok Pisin. They are used as a vernacular for informal occasions and have yet to develop a full repertoire of registers – linguistic styles associated with context of use. Newspapers such as *The New Straits Times* (Malaysia), *The Straits Times* (Singapore), and *The Hindu* (India) use native English in their stories, which may contain linguistically trivial neologisms characteristic of the local cultural milieu. Literary works are also written in native English; nonnative varieties are used in the speech of characters as an indexical marker of their low social and educational standing (Talib, 2002). The thin repertoire of registers of a typical nonnative variety is

Table 2 Counts of *already* in private conversation and writing, normalized to 1000 words of text

	Medial position		*Final position*	
	SIN	GB	SIN	GB
Spoken register	0.42	0.18	0.98	0.04
Written register	0.39	0.37	0.02	0.02

Note. SIN, Singapore English; GB, British English.

correlated with its limited grammatical resources, its historical roles, and its present sociolinguistic status.

The lack of registral variation is supported by available corpus evidence. Table 2 displays the frequencies of *already* in the spoken and written registers of Singapore English (SIN) and British English (GB). The data are culled from the International Corpus of English (Greenbaum, 1996). (See Table 3.)

There is no difference in the written register. Differences emerge only in the spoken register of Singapore English, especially in the sentence-final position. The corpus profile suggests a clear registral division of labor: substrate-driven grammatical innovations are used in informal contexts and avoided in formal contexts.

Table 3 Examples of *already* from the Singaporean component of the International Corpus of English

With dynamic predicates
1. Maybe she increase the price *already*
2. I told you about it *already* remember

With stative predicates
3. It's like kind of oldish *already*
4. Her hand better *already*

Habitual states
5. Nowadays I switch to Mandarin *already*
6. I think I am quite used to it *already*

With negatives
7. By the time you eat nuh not nice *already*
8. Aiyah I cannot remember *already*

In coordinate sentences
9. When I was in sec one I noticed him *already*
10. If reject then she wouldn't get her PP *already*

Stigma and Grammatical Growth

One reason for the underdeveloped state of the nonnative variety is the lack of prestige in the adoptive speech community. Even in places such as Singapore, where English is the *de facto* national language and the local accent is increasingly seen as a marker of the Singaporean identity (Ooi, 2001), grammatical features that deviate from native English are stigmatized and frequently targeted for eradication in government-sponsored *Speak Good English* movements. Stigmatization has serious consequences for the nonnative variety. Not only do stigmatized features face individual and institutional resistance, they are also slow to stabilize for eventual codification (Bao, 2003). Nonnative varieties need to overcome stigma, reduce internal variation, and expand linguistic resources before they are able to function in wider communicative domains. Against the international prestige and dominance of native English, this is no easy task.

Theoretical Approaches

The bulk of the literature on nonnative varieties of English is devoted to sociolinguistic issues arising from the global spread of English, among them identity, ownership, standardization, and English pedagogy (Quirk and Widdowson, 1985; Cheshire, 1991; Kachru, 1992; Fishman *et al.*, 1996; Görlach, 2002). The cause of grammatical restructuring is also the subject of intense study and lively debate, especially among scholars of pidgins and creoles. Some scholars treat all varieties of English as adaptations to their environment, so the tripartite division – native, nonnative, and pidgin and creole – has little theoretical significance (Mufwene, 1994).

Among the many factors that are involved in grammatical restructuring, we can list linguistic universals, markedness conventions, internal drift, and language acquisition. Also crucial is the role of the languages in the contact ecology, especially the linguistic substratum. The continued presence of indigenous languages in the speech community of a nonnative variety gives added importance to substrate transfer as a prime mover of grammatical restructuring (Lefebvre, 1998). At the same time, native English exerts strong normative pressure. The antagonistic forces on the grammar of the nonnative variety cannot be resolved purely on linguistic grounds. Grammatical restructuring is a composite and complex process, and no single mechanism is solely responsible. For recent summaries of the field, see Thomason (2001) and Winford (2003).

Introduction: Creole Myths

Pidgins and creoles have long been characterized as ungrammatical and their speakers as uneducated. This bias is illustrated in the following excerpt from the first novel completely written in a French-based creole (Guyanais), a stinging satire of French colonial society in Cayenne offered through the voices of two Creole characters: Atipa, a gold miner, and his friend Bosobio:

(1) **Atipa:** Nu kriol pa gen reg ku franse
We creole not have rule like French

(2) nu sa pale li ku nu wle…
we TOP speak it as we want

(3) gremesi bunge landan nu lang
Thank god in we language

(4) nu pa benzwen okjupe di sintas…
we not need worry of syntax

(5) Mo rin save sintas-la sa lang ye
me nothing know syntax-DET TOP language that

(6) ka pale la konsey ke la tribinal
IMPERF speak DET council like DET tribunal

(7) **Bosobio:** a pu sa li gen un ta di zafe
TOP for that it have one lot of business

(8) mo pu ka konpren ni la tribinal ni la fomasi-la
me not IMPERF understand neither at tribunal nor DET pharmacy-DET

Atipa: 'We Creoles do not have grammatical rules as in French, we speak just as we like. Thanks to God who gave us our language, we don't have to worry about syntax. I don't know anything about syntax, it's the language they use at council meetings, and at the tribunal. **Bosobio:** That's why there are so many things I don't understand, either at the tribunal, or the pharmacy.' *Atipa* (Parépou, 1885)

Atipa's anonymous author, who used the pseudonym of Alfred Parépou, neatly summarizes the myths attached to creoles, and their social correlates: creoles are not real languages ('we speak as we want'; 'creole has no syntax'); furthermore, creole speakers are excluded from official business and basic social services. Yet, the author demonstrates that this nonlanguage can be used to write a 227-page novel!

The young languages we call pidgins and creoles are universally engendered in the context of traumatic situations such as slavery, indenture, or migration. Although pidgins and creoles differ in the scope of their social functions – pidgins are short-term creative attempts at producing *lingua franca*s, whereas creoles are native vernaculars – they have in common that they are oral languages spoken by marginalized groups, are rarely acknowledged as valid grammatical systems, even by their own speakers, and are

Variation in Pidgins and Creoles

G Escure, University of Minnesota, Minneapolis, MN, USA

© 2006 Elsevier Ltd. All rights reserved.

Introduction: Creole Myths

Pidgins and creoles have long been characterized as ungrammatical and their speakers as uneducated. This bias is illustrated in the following excerpt from the first novel completely written in a French-based creole (Guyanais), a stinging satire of French colonial society in Cayenne offered through the voices of two Creole characters: Atipa, a gold miner, and his friend Bosobio:

(1) **Atipa:** Nu kriol pa gen reg ku franse
We creole not have rule like French

(2) nu sa pale li ku nu wle…
we TOP speak it as we want

(3) gremesi bunge landan nu lang
Thank god in we language

(4) nu pa benzwen okjupe di sintas…
we not need worry of syntax

(5) Mo rin save sintas-la sa lang ye
me nothing know syntax-DET TOP language that

(6) ka pale la konsey ke la tribinal
IMPERF speak DET council like DET tribunal

(7) **Bosobio:** a pu sa li gen un ta di zafe
TOP for that it have one lot of business

(8) mo pu ka konpren ni la tribinal ni la fomasi-la
me not IMPERF understand neither at tribunal nor DET pharmacy-DET

Atipa: 'We Creoles do not have grammatical rules as in French, we speak just as we like. Thanks to God who gave us our language, we don't have to worry about syntax. I don't know anything about syntax, it's the language they use at council meetings, and at the tribunal. **Bosobio:** That's why there are so many things I don't understand, either at the tribunal, or the pharmacy.' *Atipa* (Parépou, 1885)

Atipa's anonymous author, who used the pseudonym of Alfred Parépou, neatly summarizes the myths attached to creoles, and their social correlates: creoles are not real languages ('we speak as we want'; 'creole has no syntax'); furthermore, creole speakers are excluded from official business and basic social services. Yet, the author demonstrates that this nonlanguage can be used to write a 227-page novel!

The young languages we call pidgins and creoles are universally engendered in the context of traumatic situations such as slavery, indenture, or migration. Although pidgins and creoles differ in the scope of their social functions – pidgins are short-term creative attempts at producing *lingua franca*s, whereas creoles are native vernaculars – they have in common that they are oral languages spoken by marginalized groups, are rarely acknowledged as valid grammatical systems, even by their own speakers, and are

therefore rarely written. *Atipa* is a major exception, but even now literature fully written in creole is scarce.

This article identifies some of the linguistic conflicts and choices that face pidgin and creole speakers in their social networks. Rather than providing an overview of the wide range of variation that occurs in creole communities around the world, I will focus on a few representative examples.

Variation in Pidgins

Pidgins are generally short-term varieties restricted to specific social domains or occasional events such as seasonal trade activities. Pidginization has often been defined as 'imperfect' acquisition of the target language, but this characterization is debatable. The objective in any of the emergency situations that give birth to new varieties is basic communication, not native-like fluency in the dominant language. If one accepts this pragmatic goal as a realistic option, it is clear that linguistic variability must have been present from the very beginning of the contact.

Since the rapid production of an operational lingua franca is crucial, and happens without the benefit of proper instruction, pidgin development can be expected to be highly variable. Some of the strategies widely used in pidginization are illustrated in the following sample of CPE (Chinese Pidgin English), a lingua franca that developed in the 19th century as British ships traded in Canton, and Cantonese (Yue)-speaking Chinese (Chinese, Yue) merchants and servants made the effort to communicate in English with Europeans. CPE evidence is represented in a large number of occasional (and not necessarily accurate) observations made by Europeans. CPE combines English lexicon and Chinese substratal influences, such as paratactic structures rather than subordinating syntax, the use of elements such as *suppose* to separate propositions, and of classifiers such as *piece* before nouns. Some of these features occur widely in pidgins (and creoles), but others do not, and are thus traceable to transfer from Chinese, such as the usage of a classifier in (15). Variation is illustrated below in sentences excerpted from a large unpublished corpus made available by Philip Baker (CPE Corpus, 2004). The pidgin sometimes functions as a pro-drop language (absence of subject pronouns in [9–10, 13]), but sometimes not, using indiscriminately subjective or objective pronouns, since Chinese has no case marking (2004: 11–12) [translation is provided only when the meaning may be unclear]:

(9) This have every poor place, and very poor people; no got cloaths, no got rice, no got hog; no got nothing; only yam, little fish, and cocoa-nut; no got nothing make trade, very little make eat.

(10) No got fowls, have got chicken [. . .] no can tell, must first makee weigh.

(11) Me think have go Pekin.

(12) Suppose he have no got eye, how can him see? Suppose he no can se, how can him walkie?

(13) Suppose cheat a little can do, suppose cheat too muchy no can.

(14) Suppose no gib lice, how can lib?
'If you don't give me rice, how can I live?'

(15) One piece man [. . .] How much piece masts hab got you ship, how many piece guns, shot and powder? How much piece woman, cow childes and bull childes?
'One man [. . .] How many masts have you got on the ship, how many guns, bullets and powder? How many heifers and calves?'

Variation in Creoles

Since creoles are more numerous and better documented than pidgins – but note that many contemporary creoles are called 'Pidgins,' such as Nigerian Pidgin, or Tok Pisin – the remainder of the article will discuss two related issues that have lately dominated the field of creole studies.

First, the reality and structure of the 'creole continuum' is examined. Creoles (like pidgins) were never isolated from their lexifiers. The social background of native creole vernaculars was such that their subaltern speakers were always in contact with the language of dominant social strata, but in differential ways. Some individuals (i.e., house slaves) had better access than others (field slaves) to the target language (TL), which may have been either socially or demographically dominant. Moreover, the available TL was not necessarily the standard (or prestigious) version of the lexifier: it may have been a nonstandard variety of the European language(s), for example, in contacts between slaves and overseers or ship hands, and thus learners of different varieties were likely to interact and use different versions of the TL as *lingua franca*. In addition, demographics (such as relative proportion of European speakers of the TL and Africans in contact) determined the outcome of the creolization process during the formative period (Chaudenson, 1992). The proportions of speakers

varied according to the region or the household, which explains the linguistic differences between neighboring varieties – e.g., between Morisyen (in Mauritius) and Réunionnais (Réunion Creole French; in Réunion), both in French-colonized islands in the Indian Ocean; or between Jamaican Creole and Bajan (Barbados), both spoken in English-colonized Caribbean islands. In those two parallel cases, whites outnumbered slaves in Réunion and in Barbados, but the opposite was true in Mauritius and Jamaica. Consequently, Morisyen and Jamaican are more 'creolized' than their counterparts. This designation means that the most basilectal varieties in Mauritius and Jamaica have no equivalents in Réunion and Barbados: Bajan and Réunionnais have more restricted repertoires, ranging only between mesolects and acrolects.

Linguistic variability is to be expected at every stage of the language history. Most previous colonies remained economically dependent on European (or other) nations, even after independence was granted. Because of the continuing contiguity of prestigious and stigmatized varieties – greatly facilitated by the greater availability of education – language stabilization is counterintuitive in any creole context, which does not exclude the existence of a regular creole system. Similarly, single-style speakers are rare, even in remote rural areas. However, some varieties called 'radical creoles' (Saramaccan for example) are assumed to be somewhat stable, restricted to conservative varieties, and not associated with a continuum. This situation may be the consequence of group isolation, as suggested by Atipa in the Guyanais quotation shown above, but it is doubtful that such social contexts still exist. With some rare exceptions, the concept of the creole continuum effectively captures the flexible reality of contact vernaculars.

Secondly, the issue of 'decreolization' – that is convergence toward the dominant language, and concomitant loss of the creole – is re-evaluated. Although pidgins generally disappear, or evolve into more complex varieties, many creoles thrive and retain high covert prestige in their native communities, even as they interact with dominant or official languages.

The Creole Continuum

Since creoles are still overwhelmingly considered by public opinion to be corruptions or distortions of official languages, speakers of those marginalized varieties are bound to acquire some version of the local standard. Literacy is widely available now, and the 'proper' medium of instruction is naturally the official language (e.g., English in Belize; French in Martinique, Portuguese in Cape Verde, etc.). However, the standard model is rarely present in the classroom, as local teachers have variously acquired their own version of the standard, thus contributing to the continued linguistic variability observable in creole areas.

Early pioneering studies viewed creoles as static nonstandard approximations of their lexifiers. This perspective implied that creole speakers consistently used a predictable nonstandard system. But a few innovative analyses of creole variation led the way to a more realistic understanding of linguistic repertoires. DeCamp (1971) in his description of Jamaican Creole was the first to use the concept of continuum as an analytical tool in complex linguistic situation. He referred to a wide range of linguistic options that were available to the creole speaker, as illustrated in variants such as: *mi tel am/a tel im/a told him*, pointing out the lack of clear separation between variants, and the myth that there are only two varieties of language.

Pidgin and creole speakers are constantly fluctuating between two poles, the vernacular, which is appropriate in familiar, at home and in group situations, and the formal standard, which is required in official contexts, typically work and out group situations. But speakers' repertoires are not restricted to two clearly bounded varieties; they spread over a continuum of overlapping forms, whose specific representations are dictated by the social, ethnic, or gender contexts, the competence and adaptability of individual speakers, and other psychological factors. The 'creole continuum' aptly captures the absence of any clear boundary separating the various speech types available within any Creole community.

This continuum can be divided into three broad variety groupings (or 'lects'): 'basilects,' 'mesolects,' and 'acrolects.' Basilects are the most vernacular varieties that linguists have typically described as creoles. Acrolects are often used to refer to Creole speakers' production of the local standard language, yet they are not identical to that standard; they are usually L2 versions of the standard. Finally, mesolects are located somewhere between basilects or mesolects, yet are not imperfect approximations of the acrolect. Mesolects have their own structure and their own *raison d'être*.

Bickerton (1975) was probably the first to complete a comprehensive analysis of the language spectrum for Guyanese Creole (English-based creole), and his novel approach stimulated a number of creole studies that adopted the concepts of continuum, and the related notion of implicational scales, as analytical devices. To cite just a few studies of English-based creoles: Washabaugh (1975), Herzfeld (1978), Craig (1980), Escure (1981), Singler (1984), Rickford

(1987), Crowley (1990), Patrick (1992), Aceto (1996), Smith (2002). Studies of French-based varieties include Ludwig (1989), Chaudenson (1992), Lefebvre (1998), Corne (1999), and many more. Some examples of variability across creole continua are provided below, illustrating variation in lexical semantics, phonology, and morphosyntax in samples taken from two English-based creoles, Ghanaian Pidgin English (West Africa) and Belizean Creole (Central America).

Lexical Semantics

The naming of body parts offers a well-known example of semantic differentiation at the word level. Many creoles display substrate influences in the naming of limbs, with the transfer of African semantic structures into Indo-European lexicon: thus, following Bantu and Kwa practice of using one single word to refer to the whole limb, English-based creoles (Belizean, Jamaican) use *fut* to refer to both 'foot' and 'leg', and *han* to refer to 'hand' and 'arm' (but Nigerian Pidgin used *leg* for both 'foot' and 'leg', though it uses *han* as the generic upper limb term). In Portuguese, creoles such as São Tomé, the equivalent Portuguese words are used with the same semantic range. The same feature occurs in Bislama (also English-based, spoken in Vanuatu), though the substratal influence is Austronesian in this case. When speakers of those creoles switch to acrolects, they then use the appropriate term. For example, a Creole boy (in Belize) said (showing his calf): *Wan shaak bait mi fut hia*, 'A shark bit my leg here,' but in the next minute, he switched to an acrolect: *Main da maskito pan yu leg,* 'Mind that mosquito on your leg' (Escure, 1990).

Education and Lectal Level (Ghanaian Pidgin)

The short dialogue shown below, taken from a radio commercial in Accra, Ghana, illustrates particularly well subjective attitudes toward the varieties available to creole speakers: the creole (Ghanaian Pidgin) is attributed to the uneducated speaker (taxi driver), while the engineer speaks Standard Ghanaian English (acrolect). The transcription represents basilectal features in the driver's speech: phonological features (absence of interdentals, absence of postvocalic /r/, and of /h/), morphosyntactic features (use of preverbal imperfective *de,* unmarked past, relativizer *we*, single preverbal negative element). On the other hand, the engineer uses 'flawless' English grammar (but Huber's audio version reveals acrolectal phonetic variants):

(16) **Driver**: ju sabi ma padi adzeman, i de draiv tata bos we in masta bai fo hia
'You know my friend Agyeman, he drives a Tata bus that his master bought here'

(17) **Engineer**: The Yellow Cab Company Ltd?

(18) **Driver**: jes, i no de bring am fo sevisin en mentenans, en i de poches in spepas fo evriwea.
'Yes, he doesn't bring it here for servicing and maintenance, and he buys his spare parts from everywhere'

(19) **Engineer**: Is this Tata vehicle on the road?

(20) **Driver**: No, i de brok daun plenti-plenti.
'No, it keeps breaking down. (Huber, 1999: 271)

Lectal Variation (Belizean Creole)

A few texts drawn from an unpublished Belizean corpus by Escure (1990) illustrate the extensive range of the creole continuum, starting with the most extreme lects, basilects and acrolects, then addressing the elusive mesolect.

Basilect (Nansi Story)

Miss Dolly (a 60-year old woman from Placencia) tells a traditional tale (Nansi story). This story evidences some prominent basilectal features:

- The use of the preverbal aspectual morpheme *de* (e.g., *everibadi de dans* 'everybody dances/keeps dancing') is best defined as an imperfective, as it may have progressive and habitual/iterative functions.
- The nonmarking of past (e.g., *di dans stat tu brok op* 'the dance started to break up.'
- The creole reinterpretation of some old preterites as bare verbs (e.g., *brok* 'break').
- The occurrence of a different preverbal past morpheme *me* (sometimes with anterior value), which helps distinguish between two sequential past events (*di mjusik me de ple* 'the music was playing' as background event to the crowd leaving the dance-hall). Here, the past morpheme is also combined with the imperfective marker indicating continuing action (see Escure, 2004 for a more complete list of basilectal features).

(21)

Dis	da	wan	taim	nou	dei	had
This	*TOP*	*a*	*time*	*now*	*they*	*had*
wan	dans	evribadi	de	dans		
a	*dance*	*evrybody*	*IMPERF*	*dance*		

'Once upon a time, they had a dance, everybody would dance'

(22) bra taiga bra dag bra everibadi
Brother Tiger Brother Dog Brother Everybody
dans Evribadi de dans
so Evrybody IMPERF dance
'Brother Tiger, Brother Dog, Brother Everybody, so everybody would dance'

(23) buldag de dans kou de
bull dog IMPERF dance cow IMPERF
dans evribadi
dance everybody
'the bulldog dances, the cow dances, everybody'

(24) big pati de goun tuwad midnait nou
big party IMPERF go.on towards midnight now
di dans stat tu brokop
the dance start to break.up
'it's a big party, towards midnight the dance ended'

(25) bika wan fait stat evribadi stat tu fait
because a fight start everybody start to fight
'because a fight started, everybody started to fight'

(26) evribadi de tekdun dem bati
everybody IMPERF take. down DET butt
an de kot
and IMPERF cut
'and everybody started to go and they left'

(27) an dat waz di en a di pati
and that was the end of the party
'and that was the end of the party'

(28) bot di mjuzik we me de plei
but the music that ANT IMPERF play
'but the music that was playing'

(29) i go laik dis: zinzinzin. vajalin
it go like this: zinzinzin. violin
da me di mjuzik
TOP IMPERF the music
'it went like that: *zinzinzin* it's the violin that was playing' (Nansi story, Escure, 1990)

An additional example shows how creole marks irrealis modality (unrealized events) through the combination of the anterior marker *me* and the future marker *wan* – a grammaticalized from of the verb 'want':

(30) R. wan tek wan korespondens kos.
R. FUT take a correspondence course
'R. will take a correspondence course.'

(31) i me wan tek it befo i kum awt.
he ANT FUT take it before he come out
'He would have completed it before he graduates.'

(32) i me de plan fu tek it
he ANT IMPERF plan to take it
'He was planning to take it'

(33) da di taim de tem don di kos don.
that the time the term done the course done
'so that by the time the term is over, his course would have been completed.' (Escure, 1990)

Acrolect

The acrolect is a local standard that differs from external standards. Since acrolects are typically the result of late acquisition, probably through school education, inconsistencies are most likely to occur at this lectal level, depending on social factors, such as an individual's relative access to the standard, or psychological factors, such as the speaker's identity and intent to converge toward the standard. The acrolect generally differs phonetically from its lexifier (in the case of Belizean English, it differs from RP-British English). Most common distinctions include the systematic or occasional absence of interdental fricatives, and variation in vowels (for example, lack of distinction between tense and lax vowels). Acrolects generally use standard grammar and morphology, for example, past verbs are now marked, preverbal morphemes are absent, the copula *be* is introduced, and so forth, but more variation occurs in upper mesolects, that vague area between the widely used labels of 'English' and 'broken English.' Thus, nonstandard morphological features may be part of an acrolectal version (for example, absence of copula/auxiliary; lack of 3SG agreement; hypercorrect past inflection, or pronoun variation), as are pragmatic mechanisms (such as the fronting of topics). The following sentence displays both *be* presence (*dei were expectin*) and absence (*would willin*):

(34) Dei we espektin samwan den wu
They were expecting someone then who
wud wilin tu tekop amz
would willing to take.up arms
'They were expecting someone who would be willing to take up arms.' (Escure, 1990)

Newspapers often exhibit similar linguistic features, whether unwittingly or as intended for special effect:

(35) I can **recalled** a very shocking incident [...] One may come to the conclusion that an abundance of ignorance **exist** within [...] This area has long been mean, but never **have** it been so lethal [...] Such an attitude gathers strength from its own **existent**, the longer it **persist**, the deeper **it** roots grow. ('Help our troubled & lost generation' *Alkebulan* (Belize), January 21, 1994: 2)

But an article on local politics – discussing the rival political party (PUP) – inserts some basilectal phrases in the middle of a standard text for emphasis (here sarcasm, shown in bold characters in the original text):

(36) [...] their plaintive wail when all else fails is victimization, translation**: A fri'ten bad.** [literally, I frightened bad 'I am afraid']

(37) [. . .] Houses are being built [. . .] **And would you believe it, the PUP bex bout that**. [literally, PUP vexed about that 'the PUP is annoyed about that'] ('The observer' *The People's Pulse* (Belize), April 17, 1994: 14)

Mesolect (The Village Midwife)

Mesolects can be defined as intermediate varieties, but they are not mere approximations of the standard: they have their own internal motivation and place in the social life of continuum users. Individuals who control the whole range of the continuum select the mesolect in well-defined situations – when addressing an older person, or the members of another ethnic group, or dealing with a serious topic. There are issues of respect, of formality, and of identity involved in such choices, so it is not possible to speak of 'basilectal' or 'mesolectal' speakers, except to say that in context A, an individual is a basilectal speaker, but in context B, the same speaker is a mesolectal speaker.

In the following excerpt, Miss Dora, a 75-year old midwife who has delivered all the village babies for the last 50 years, uses neither a basilect not an acrolect. She has native competence in the creole vernacular, but selects the mesolect when recounting her professional activities with her nephew. Characteristics of this mesolect include absence of copula, unmarked past, and an occasional preterite form (*had*) as well as the auxiliary *don't* (instead of simple preverbal negative). Mesolects generally imply avoidance of basilectal morphemes, but this implication is not always the case: at crucial peaks of the narrative, Miss Dora uses the TMA creole morphemes *de* (Imperfective) *me* (Past Anterior), as well as the expression *don ded* 'completely dead', a common use of the perfective marker 'done' to emphasize the finality of death. Note also the creole use of *lef* for 'leave' (*I had to lef dat* 'I had to leave/stop that'), one of a few verbs whose neutral form is a relexified irregular preterite.

(38) Da sem taim tu peshen kum in
At same time two patient come in

(39) wan mada da di ilevent bebi im gat
a mother TOP the eleventh baby she got
en di ada wan da di naint
and the other one TOP the ninth

(40) en de riali nat sapoz tu got bebi da vilidg
and they really not supposed to get baby at village

(41) bot den dei don wan go da haspital [. . .]
but then they don't want go to hospital

(42) wel a had a fait wid di bebi
well I had a fight with the baby
bika di bebi hed kum
because the baby head come

(43) bot di ada paat a di bodi wont kum [. . .]
but the other part of the body won't come

(44) den di aftabat kyan kum
then the afterbirth can't come

(45) a had tu lef dat wan an di ada wan redi
I had to leave that one and the other one ready

(46) a swab shi af [. . .]
I swab her off

(47) an den shi lef wika stil
and then she stay weaker still
de hemoredg
IMPERF hemorrhage

(48) an wen a give shi dat an fainali i kwait dawn
and when I give her that and finally she quiet down

(49) an shi an mai sista me tink di
and she and my sister ANT think the
bebi don ded
baby PERF dead

(50) a do mawt tu mawt bridin an
I do mouth to mouth breathing and
di bebi big bwai naw.
the baby big boy now

'Two patients came in at the same time. One mother was delivering her eleventh baby, and the other her ninth [. . .] They are not really supposed to deliver in the village, but they don't want to go to the hospital [. . .]. Well I had to struggle with the (first) baby because its head was coming out, but not the rest of its body [. . .] then the afterbirth wouldn't come [. . .] I had to leave that one (first mother) to go to the other one who was ready (to deliver) [. . .] I cleaned her (second mother) up [. . .] (first mother) remained weak, and was still hemorrhaging [. . .] When I gave her (herbs) she (first mother) finally settled down. She and my sister thought that the baby was already dead [. . .] But I did mouth-to-mouth resuscitation, and the baby is now a big boy.' (The Village Midwife, Escure, 1990)

Decreolization

Schuchardt's 'life cycle' concept (1883) became DeCamp's 'postcreole' continuum (1971). This developmental hypothesis suggests that creoles eventually merge with the standard, assuming that the continuum is the result of decreolization (loss of the creole). However, the data presented above suggest that the acquisition of acrolects or near-standard varieties – obviously facilitated by access to education and standard speakers after emancipation – does not necessarily entail concomitant loss of basilectal segments. Individuals, with few exceptions, are generally found to control a wide repertoire. Empirical studies show that they don't lose their native variety just because they have acquired a new one – no more than L2 acquisition would entail

loss of L1, except in extreme situations leading to language death.

The ability to handle alternate codes has been explained in terms of the 'dual standard,' or the 'covert' vs. 'overt prestige' dichotomy: as subaltern groups gain access to education, they become increasingly motivated or obligated to learn the standard as a means of improving their social position. Creole values may thus be overtly despised but secretly respected, whereas the values of the high-status group are overtly respected and secretly despised. As is the case in any multilingual context, individuals make linguistic choices that reflect their allegiance or close associations with either the dominant social group (usually speaking standard varieties), or the peer group, or both. The 'linguistic market' sociological model of linguistic production and expression also captures the relation between linguistic system (*l'habitus linguistique*) and linguistic market (*le marché linguistique*) (Bourdieu, 1982).

Such perceptual differences still mirror the historical colonial bias and the shift to a new social order. They also explain why creole languages offer such a wide range of linguistic possibilities. The linguistic spectrum captures the multiple nuances required in various human contact situations. The very nature of its flexibility ensures that **all** varieties remain active and operational, and contradicts the view that there is an ineluctable move toward the standard, since native (basilectal) values are highly prized, though covertly.

According to this perspective, decreolization is not diachronic change (although regular change naturally occurs), but rather repertoire extension and code switching. There is no postcreole continuum if the creole is still vigorous, as in Belize, or Haiti, or Papua New Guinea. There is a postcreole situation when the creole has lost most of its speakers, as in Louisiana, in which the confusion of the French-based creole with Cajun (a French Canadian dialect), the import of French teachers from metropolitan France, the dominance of English, and generally the low status of black speakers have probably contributed to the receding state of Louisiana Creole.

Conclusion

The field of creolistics has expanded considerably as new sociohistorical sources have redefined our understanding of the early stages of language genesis and development, and as more empirical field studies have offered testing grounds for theoretical and sociolinguistic models of language use and language development. Subfields of linguistics (historical linguistics, sociolinguistics, and theoretical linguistics more specifically) can benefit from the current state of knowledge in pidgins and creoles. New creoles encapsulate the linguistic effects of the violent social history that most of humanity has been subjected to. Language development is closely dependent on the economic and political features of the societies in whose context they emerged, and current linguistic variability serves to illustrate further the correlation that exists between linguistic structures and social aspects. Creole speakers use polylectal systems, rather than monolithic grammars, and this aspect should be highly relevant to theoretical models that focus on abstract generalizations but overlook the human language ability to juggle multiple systems.

Variation in Second Language Acquisition

I Tsimpli, Aristotle University of Thessaloniki, Thessaloniki, Greece

© 2006 Elsevier Ltd. All rights reserved.

The linguistic behavior of the L2 speaker is commonly believed to differ from that of the native speaker. The differences involve several aspects of language: grammar, pronunciation, and social and pragmatic features of language use. Moreover, these differences are both qualitative and quantitative, especially in early stages of L2 development. Grammatical, phonetic, and pragmatic deviations from the target L2 are obvious in learners with relatively little exposure to the second language. On the other hand, in advanced stages of second language development, the L2 learner may even attain native-like performance at least in the domain of grammar use (Birdsong, 1992; Epstein *et al.,* 1998; Sorace, 1993, 2000).

Throughout L2 development – perhaps with the exception of beginning stages – the learner's behavior generally includes target-like uses, whose frequency increases with time. In advanced stages, the comparison between the native speaker and the L2 speaker of that language becomes considerably more difficult. Empirical research on L2 grammatical development has shown that even advanced L2 speakers may differ from native speakers of a language in the degree of (in)consistent use of target forms, or in the (in)consistent application of grammatical constraints on the use of L2 grammar (cf. Coppieters, 1987; Hawkins *et al.,* 1993; Sorace, 1993, 2000; White and Genesee, 1996). This variation is also termed 'optionality' or 'variability' and refers to the performance data of the individual L2 speaker.

This notion of variability seems to be distinct from the notion of individual variation or individual differences. These terms aim to describe variation among L2 learners who have been grouped under the same level of L2 performance, on some independent measure of evaluation (e.g., a placement test). The degree of individual variation among L2 learners has also been used as a criterion for distinguishing first from second language development. Child L1 learners follow a relatively uniform developmental pattern and attain a mature level of competence in their native language. In the generative linguistics tradition, this uniform, fast, and effortless process of L1 development, together with the uniformity of the outcome referred to as native speaker's competence, are viewed from the same theoretical perspective: the innateness hypothesis for language acquisition. The lack of uniformity in the outcome of L2 acquisition, on the other hand, gives rise to alternative hypotheses regarding the nature of the cause. Several possibilities have been offered, which are addressed below. In

Variation in Second Language Acquisition

The linguistic behavior of the L2 speaker is commonly believed to differ from that of the native speaker. The differences involve several aspects of language: grammar, pronunciation, and social and pragmatic features of language use. Moreover, these differences are both qualitative and quantitative, especially in early stages of L2 development. Grammatical, phonetic, and pragmatic deviations from the target L2 are obvious in learners with relatively little exposure to the second language. On the other hand, in advanced stages of second language development, the L2 learner may even attain native-like performance at least in the domain of grammar use (Birdsong, 1992; Epstein *et al.,* 1998; Sorace, 1993, 2000).

Throughout L2 development – perhaps with the exception of beginning stages – the learner's behavior generally includes target-like uses, whose frequency increases with time. In advanced stages, the comparison between the native speaker and the L2 speaker of that language becomes considerably more difficult. Empirical research on L2 grammatical development has shown that even advanced L2 speakers may differ from native speakers of a language in the degree of (in)consistent use of target forms, or in the (in)consistent application of grammatical constraints on the use of L2 grammar (cf. Coppieters, 1987; Hawkins *et al.,* 1993; Sorace, 1993, 2000; White and Genesee, 1996). This variation is also termed 'optionality' or 'variability' and refers to the performance data of the individual L2 speaker.

This notion of variability seems to be distinct from the notion of individual variation or individual differences. These terms aim to describe variation among L2 learners who have been grouped under the same level of L2 performance, on some independent measure of evaluation (e.g., a placement test). The degree of individual variation among L2 learners has also been used as a criterion for distinguishing first from second language development. Child L1 learners follow a relatively uniform developmental pattern and attain a mature level of competence in their native language. In the generative linguistics tradition, this uniform, fast, and effortless process of L1 development, together with the uniformity of the outcome referred to as native speaker's competence, are viewed from the same theoretical perspective: the innateness hypothesis for language acquisition. The lack of uniformity in the outcome of L2 acquisition, on the other hand, gives rise to alternative hypotheses regarding the nature of the cause. Several possibilities have been offered, which are addressed below. In

general, the difference between first and second language learners is considered to be either a difference in the learning mechanisms employed in the developmental process, or an (in)ability of the learner's system to successfully analyze L2 input, resulting in a non-target mental representation of the L2 grammar (Hawkins, 2001; White, 2003). The majority of research on L2 variation attempts to account for the L2 data on these grounds.

Recent studies in L2 acquisition have raised alternative or additional possibilities to account for variation in the performance of the L2 speaker. These are based on two fundamental hypotheses of modern linguistic theory. The first concerns the competence/performance distinction in language. Although this distinction has been an essential part of Chomskyan linguistics throughout, it is only recently that psycholinguistics and L2 research combined their efforts to investigate the possibility of L2 variation being relevant to constraints on L2 processing (production or perception) rather than on L2 knowledge (Juffs, 1998; Juffs and Harrington, 1995; Felser *et al.,* 2003) thus investigating L2 performance as a possible cause of part or all of variation in advanced stages of L2 development. The second hypothesis draws on the new 'minimalist' direction which generative linguistic research has adopted with Chomsky's (1995) minimalist program. Minimalism offers a promising view on the architecture of the language system in relation to other domains of human cognition. From this perspective, variation in the L2 learner potentially involves problems at the interface between syntax and discourse, or syntax and morpho-phonological realization (Sorace, forthcoming; Prévost and White, 2000; Goad and White, 2004). Furthermore, the combination of these two hypotheses leads to the possibility of investigating variation in the L2 speaker's grammar as a result of interface problems (morphological or syntactic) in execution, i.e., in production or comprehension, but not in the underlying linguistic knowledge.

Whatever the analysis, it is noteworthy that the two notions of variation, i.e., variation in an individual L2 speaker's grammar or variation among L2 speakers' performance, could amount to the same psycholinguistic property of the non-native language. In other words, a feasible analysis of variability in the use of a syntactic phenomenon by a non-native speaker should be extendable to account for variation found among L2 learners. As we shall see below, to approach the question of variability one needs to have an elaborate theory of language use that makes underlying grammatical representations only one of the many possible loci of variation in language performance.

In the following sections, some of the recent theoretical trends of L2 speaker variation in the use of grammar will be presented. They belong to the different but complementary research hypotheses outlined above, namely the grammar, the interface, and the processing approach.

The L2 Grammar

Earlier work in second language acquisition has revolved around the question of whether the developing L2 grammar and its endstate are constrained by natural language principles, as is the case with the native language grammar. This question refers to the nature of the learning mechanisms involved in L2 acquisition which guide the analysis of the input but also the construction of the L2 grammar. To this aim, different types of developmental L2 data primarily from adults but also from children and adolescents were examined with two points of reference; the target language on one hand, and Universal Grammar – i.e., natural language principles – on the other. There are three logical possibilities in this respect, namely that second language development is (i) similar, (ii) different, (iii) partly similar to native language acquisition, insofar as accessibility of principles and constraints of Universal Grammar is concerned. Unsurprisingly, all three possibilities have been advocated under the names of *Full Access*, *No Access,* and *Partial Access* theory, respectively (White, 2003). Within each of these theories, a number of alternative analyses have been proposed, which, however, share the basic assumptions regarding the nature and the locus of the L2 representation. Thus, *Full Access* theories propose that L2 grammars are represented in the same cognitive faculty as L1 grammars, i.e., the Language Faculty. All learning mechanisms and constraints on developing and on endstate native grammars are similarly operative in the L2 case. These theories have an important epistemological advantage over No Access and Partial Access theories, in that they assume the 'null hypothesis' for second language acquisition, Specifically, by arguing that the cognitive domain of linguistic knowledge is the same for native and non-native languages, they propose a more economical approach to knowledge acquisition and storage. Moreover, they have an empirical advantage in explaining the fact that all L2 learners, exposed to sufficient input, will attain good knowledge of the second language, which can be used spontaneously and without conscious feedback from explicit metalinguistic information. On the other hand, Full Access theories need to account for variation in the use of the L2 grammar by even advanced learners. To this

end, they propose that variation can be (a) due to the insufficient or degenerate nature of the input presented to the L2 learner, (b) to the 'marked' status of the L2 phenomenon in relation to universal constraints (c) to L1 interference at interface levels of representation. The third choice belongs to the interface approach to L2 variation and will be discussed below. The nature of the input and the extent to which the L2 learner's developing grammar can analyze it adequately is an empirical question and requires experimental testing. The idea is that even if the quantity and quality of the input are similar in native and non-native learners of the same language, the fact that the non-native learner already has an endstate representation of the native language may render the L2 input underdetermined for the L2 developing grammar (Schwartz and Gubala-Ryzak, 1992). Finally, the second possible cause of variation in the L2 speaker refers to the characterization of the L2 grammar as the marked option with respect to a particular phenomenon. For example, it has been argued that null subject languages, such as Spanish, instantiate the unmarked option of the relevant parameter whereas the English non-null subject option is 'marked.' Thus, L2 acquisition of the 'marked' option should be slower or even incomplete for native speakers of null subject languages, whereas the opposite case, e.g., English learners of Spanish, would be more successful.

No Access theories maintain that the language faculty is only indirectly involved in L2 grammar construction, i.e., only through positive transfer of grammatical features or parametric values that are similar in the native and the second language. The crucial difference between No Access and Full Access theories is the assumption that general learning mechanisms may be implemented in the analysis of the L2 input and the construction of the L2 grammar (Clahsen and Muysken, 1986). This approach implies that the L2 grammar may be represented in a cognitive domain distinct from the L1 grammar, in adult L2 learners. As a result, variation in the performance of the L2 speaker is expected: a linguistic generalization drawn from general cognitive strategies, distinct from the language faculty, will give rise to wrong performance, even if the rule is consistently observed. This is due to the notions of domain-specificity and modularity of the language faculty. Grammar-construction located outside the language faculty is bound to show defects compared with the usual development of the native language, in the same way that compensatory strategies implemented by cognition in domains affected by some pathological cause can give rise to incomplete output representations (Paradis and Gopnik, 1997).

Partial Access theories share the assumption of Full Access theories regarding the role of UG constraints in L2 grammar construction. Thus, L2 development is regulated by the same language-specific mechanisms operative in L1 acquisition. Second language grammars are, then, 'natural languages,' represented within the domain of the language faculty. On the other hand, Partial Access theories suggest that syntactic differences between the grammar of the native and the second language are problematic even for advanced learners. The reasons are various. For example, some Partial Access theories assume that the Critical Period Hypothesis is valid and, as a result, constructing the target L2 grammar even on the basis of sufficient input is impossible for adult L2 learners. The underlying assumption is that certain aspects of the language faculty are subject to critical period constraints. These aspects become inaccessible after the end of the critical period, and the system maintains the syntactic choices of the native language for the L2 grammar, too. In advanced stages of L2 development, the L2 grammar attempts to compensate for the misfit between the L1 grammar and the L2 input, adopting other UG-constrained options or using metalinguistic strategies to accommodate the L2 input (Smith and Tsimpli, 1995; Hawkins and Chan, 1997). It is important to note that variation in the performance of the L2 speaker is predictable by Partial Access theories. The locus of variation is the syntactic domain where L1 syntax differs from the second language. As L2 development proceeds, the learner's attempts to integrate UG-based or other options to approximate L2 input leads to improvement in L2 performance, which, however, cannot, by assumption, be identical to native-like output.

Explicitly adopting the Critical Period Hypothesis is not necessary in the Partial Access framework. It is possible to attribute the incomplete nature of L2 grammars to the mature representation of the native language which characterizes the language faculty of an adult L2 learner. Thus, it has been suggested that L2 learners are predicted to show optional and variable behavior in the use of L2 grammar due to the underlying optional grammatical representations. This optionality is due to unfixed (or 'inert' in Eubank's 1993/94 terms) values that functional categories such as inflection may have, in second language grammars. Given that the cause of optionality is the lack of fixed values of grammatical features in the L2 syntactic representations, this version of the Partial Access approach is perhaps the only one in this framework that invokes a derivational and representational difference between native and non-native grammars: the former cannot tolerate valueless features whereas the latter can. Although this theory has

been presented as a theory of developing second language grammars, a version of it has been extended to describe endstate or very advanced L2 grammars which are characterized as 'impaired' with respect to their inability to identify the value of specific grammatical features (Beck, 1998). Partial Access theories share the empirical problem of reducing variation to a minimum – albeit in a small minority of L2 speakers – and attaining an endstate grammar that is indistinguishable from that of a native speaker.

Having outlined the main assumptions of the 'grammar approach,' it becomes clear that this approach builds primarily on syntactic theory. It ignores performance factors or other non-linguistic constraints on L2 performance, on the grounds that second language grammars are analyzable like native language grammars, within the generative paradigm. If the point of reference is indeed the native language, then L2 grammars, particularly given the variability observed even in advanced stages of L2 development, should differ in both qualitative and quantitative terms. As mentioned at the beginning of this essay, however, it is possible to analyze variation in the L2 speaker as the result of an interaction between parts of the language faculty and other aspects of cognitive or motor systems, affecting language performance. We can then turn to the interface approach to L2 variation.

The Role of the Interfaces

In the recent minimalist framework of Chomsky (1995), language is viewed as a cognitive system that comprises a computational component, i.e., the syntax proper, and two interface levels: the LF (Logical Form), which includes all and only semantic information of syntactic representations, and the PF (Phonetic Form) which includes all and only phonetic output. LF is the interface between language and the conceptual-intentional systems of higher cognition, in particular, inferencing, whereas PF is the interface between language and the sensorimotor systems. Given that generative research has been based on the modularity view of the language faculty (Chomsky, 1972), the minimalist picture of language allows only the computational component, i.e., the domain where syntactic derivations take place, to remain strictly modular in the Fodorian sense. Interface levels are by definition penetrable by the systems which form the interface itself. Therefore, semantic features that 'reside' in language but also in the mental lexicon are actively involved in the LF interface. Similarly, phonetic features, which are produced by the motor system interfacing with language, have a representation in the PF interface.

An important property of interface representations is the necessary exclusion of some features which, nevertheless, participate in the syntactic computation. In particular, there are syntactic features that are *interpretable* at LF, due to their semantic content, and other syntactic features that are *uninterpretable* at LF and have to be deleted before the derivation reaches the semantic LF interface. Features such as Case or subject-verb Agreement, are responsible for crucial aspects of the syntactic derivation, but are not 'legible' by the LF interface, due to their lack of semantic content (Chomsky, 1995). Thus, in a sentence such as *This boy runs fast,* the agreement feature [3rd person singular] appears on the subject and the verb's feature specification. At LF, however, the feature is interpretable only on the subject, which is a nominal category, and not on the verb. Given that LF and PF interfaces are regulated by semantic and phonetic constraints, respectively, the elements or grammatical features that participate in the interface representations need to have semantic and phonetic content. It should be pointed out that features that are *uninterpretable* at LF are those features that drive syntactic computations and, as a result, are responsible for crosslinguistic variation in the syntax. Thus, syntactic differences between languages, referred to as 'parameters,' are regulated by the properties that semantically unintepretable features have in each natural language. The process of native language acquisition comprises acquisition of lexical, interpretable, and uninterpretable features, which will determine the parametric properties of the language acquired. This picture of the language system, together with the distinct role of a grammatical feature inside the syntactic computation and at either interface level, has proved fruitful in the description and analysis of variation in the non-native speaker of a language, as we see in the theoretical accounts framed within the interface approach.

Within the minimalist spirit, there have been some recent attempts to account for variation in the use of L2 grammar by advanced learners. There are two alternative views. One assumes that second language grammars can develop through the operation of the same UG-based principles and constraints as native language grammars. Therefore, L2 development can reach an endstate that is identical to that associated with L1 development as far as the modular representation of the grammar is concerned. This theory does not adopt critical period assumptions regarding differences in the 'ultimate attainment' of native and non-native developmental processes. It is assumed, however, that interface properties are vulnerable in cases of language contact in the individual's linguistic system. Thus, it is possible to find interference of L1 discourse-related

features on an otherwise native-like L2 representation at the LF interface (Sorace, forthcoming).

To exemplify this theoretical approach, Sorace discusses the use of subject pronouns by English near-native speakers of Italian. It appears that differences from the monolingual Italian speaker's use of pronouns are restricted to the syntax-discourse interface. Specifically, although these L2 speakers use null subject pronouns, they will occasionally use an overt subject pronoun as a response to a question such as *Perchè Maria è uscita?* ('Why has Maria gone out?), producing utterances with an overt pronoun, e.g., 'Perchè *lei*. . .' ('Because she . . .'), which are deviant, from the monolingual speaker's view, in discourse terms. This type of evidence suggests that near-native L2 speakers can be native-like with respect to the syntactic properties of the L2 grammar, but still show interference effects from the native language at the interface between syntax and discourse.

The interface level of syntax and morphology/phonology has been invoked in attempts to analyze optional use of correct morphological forms by advanced or near-native L2 speakers (Lardiere, 2000; Prévost and White, 2000). The argument, in this case, is that the constraints that necessitate use of, for example, the third person singular '–s' in English present tense forms of regular verbs (*walk-s, laugh-s*) are distinct from the syntactic representation that includes *abstract* specification of the corresponding inflectional feature. Thus, the phonological form [la:fs] is the realization of the abstract syntactic representation including the verb 'laugh' with its inflectional features (V, (3rd Person, Singular, Present Tense)). For a speaker to produce the correct form, both the abstract specification and its mapping constraints on overt morphology have to be satisfied. The interface approach to L2 speaker variation suggests that the underlying representation can be target-like, especially in the case of near-native L2 speakers, whereas the operation of the interface conditions on PF realization are affected by the surface properties of the native language. Thus, optionality in the correct use of overt morphophonology is predicted even in near-native L2 speakers.

The two versions of the interface approach presented above share a fundamental assumption, namely that the grammar of the L2 learner can be identical to that of a native speaker of the language in question. Thus, the crucial difference between the interface approach to variation and the grammar approach presented in the previous section concerns the vulnerability of the grammar proper in non-native language acquisition. One could, however, entertain an alternative account for L2 speaker variation, which is sensitive to the minimalist architecture of the language faculty, and combines some of the possibilities offered by the grammar and the interface approach. It could be referred to as the *Interpretability* approach, and it capitalizes on the minimalist assumption that grammatical features can be distinguished in terms of their role in the derivation, i.e., the syntax module, and the LF or the PF interfaces (Tsimpli, 1997, 2001). This is a more general learnability approach to grammatical features and the pattern of their acquisition in native child language learners, in non-native adults, and in pathological cases of language development.

The interpretability theory suggests that the semantically *uninterpretable* grammatical features are subject to maturational constraints in first language development. Assuming that the Critical Period Hypothesis is valid, the implication is that these uninterpretable features become inaccessible after the critical period is over. For example, the agreement feature found on verbal inflection has been associated with the value of the Null Subject parameter, mentioned above. Assuming that it is an uninterpretable feature, the implication is that it will not be accessible for parameter-resetting after the end of the critical period (Tsimpli, 1997). On these assumptions, adult L2 learners fail to construct an L2 grammar using the same resources as the child native language learner. Specifically, syntactic aspects that depend on purely grammatical features with no semantic content lead to incomplete and deviant derivations of L2 syntactic structures, even in advanced stages of L2 development. This results in the attested variation in L2 performance. On the other hand, semantically interpretable features are not subject to maturation; therefore, they are accessible to learners in any course of language acquisition. Recall also that the LF interface is not a modular system, and as such it is penetrable by higher levels of cognition, including conceptual and pragmatic information. It is therefore possible to access semantic features not only through the language system, i.e., 'bottom-up,' but through the conceptual-intentional systems, too, i.e., 'top-down.'

There are two main questions for this theory: (a) How can the theory account for near-nativeness in the use of L2 grammar; and (b) why do features of the syntax/discourse interface show variation and optional use by L2 speakers, as suggested by Sorace (forthcoming). With respect to the first question, near-native grammars are claimed to 'simulate' L2 output via linguistic or extra-linguistic routes (Smith and Tsimpli, 1995). The process of approximating near-nativeness is itself gradual. Thus, implementing alternative resources may, in the early stages of development, involve a process which is conscious or accessible to consciousness. With time and practice, the successful output becomes implicit knowledge in the

form of an over-learned routine (Anderson, 1992). For this account to be psychologically feasible, it is important to maintain that it is an empirical question which can be tested neurolinguistically and psycholinguistically, so as to access sub-conscious workings of language and systems parasitic on it, such as memory and processing constraints. Furthermore, we expect some variation to persist in the use of these grammatical features, precisely because attainment of the 'near-native' level is mediated by cognitive routes not followed in the case of the native speaker, in the form of compensatory strategies.

As far as the second question is concerned, namely the variation observed in the use of discourse-related features, there are different possibilities. The first is that these features are not part of the LF interface exclusively. Logical Form is the level of syntactic representation that includes all and only semantic features, but not discourse-related features which contribute to pragmatic interpretation. It is possible then that a higher level of representation where discourse and information-structure of the sentence are relevant, is involved. This level 'enriches' the output representation of syntax *and* LF. For example, according to theories such as Relevance Theory (Sperber and Wilson, 1995; Carston, 2002), reference-assignment to pronouns, and generally, interpretation of pronouns, is largely underdetermined by the LF interface. When this representation enters pragmatics, early stages of discourse processing will allow context to determine the referential index that the pronoun has.

Another possibility is to distinguish between the activation of an interpretable feature such as [aspect] or [referentiality] in L2 grammar construction, and the PF output of the grammaticalized options this feature has in a specific language. Consider, for example, the difference between a language that morphologically marks the distinction [+/−progressive] but not [+/−perfective], such as English, and a language that marks [+/−perfective] but not [+/−progressive], such as Russian or Greek. Both features belong to the category of *viewpoint aspect* in Smith's (1991) terms, i.e., the category of morphologically realized aspectual distinctions, which may differ from language to language. According to Smith (1991), the [progressive] feature is a subcategory of the general [-perfective] feature, in that the contexts in which the progressive interpretation is the target are also imperfective, whereas the reverse does not hold. It is relatively common for Russian or Greek near-native speakers of English to show some variation in the use of the progressive form, usually overextending it to habitual or stative cases. Sentences such as '*I am thinking that you are a fool*' are therefore possible in the advanced L2 of these speakers.

The question then is whether the problem is localized in the PF interface, the LF interface, or both. If it is a PF-interface problem, then the near-native grammar of these learners of English shows variation due to the possible mapping of the *–ing* form onto the [progressive] *and* the [−perfective]. The latter is a feature active in the native language, and the former is the feature active in the second language. Given the interpretability of these features at the LF interface, the interpretability theory predicts that the [progressive] should be accessible to the L2 grammar. Given the native language, however, the [imperfective] will also remain available. The reason why acquisition of the [progressive] does not override the L1 [imperfective] feature is primarily the subordinate/superordinate relation of these two features at the semantic level. As a result, the learner will show a certain degree of optionality even at advanced stages of development, in the morphological realization of the [−perfective, −progressive] as in the example presented above. In all contexts where the [−perfective] is active, the [progressive] may but does not need to be active too. Although the learner has acquired the [+/−progressive] distinction in the second language and can use it to contrast ongoing and habitual readings of an event, optional uses of *-ing* for non-progressive forms are also expected because of the [−perfective] feature.

In this analysis, variation in the use of aspectual forms in L2 speakers stems from the semantic interaction – at the LF interface – of [+/−progressive] and [+/−perfective] interpretable features in the second language and from the PF implications this has for the mapping options of these features onto L2 forms. If this approach is correct, variation in the use of interpretable features does not indicate problems in the *acquisition* of the relevant L2 feature. Instead, variation can be found in cases where different features of the same category are grammaticalized in L1 and L2, respectively. The co-existence and LF interaction of the native and non-native features gives rise to the variation attested.

Syntactic Processing in the Second Language

Language processing has usually held a peripheral place in generative linguistics research due to the assumption that the 'parser' is a performance system whose operations draw from grammatical knowledge but also from memory and processing constraints specific to the parser and independent from grammar proper. In native language processing, it seems that the integration of semantic and pragmatic information follows the initial step of syntactic processing; this involves generating a syntactic structure constrained

by universal and language-specific constraints on syntactic parsing, largely independent from semantic or pragmatic considerations (Frazier and Clifton, 1996; Phillips, 1996; cf. Altmann *et al.,* 1998; MacDonald, 1994). Second language research has recently begun investigating variation in the use of the second language, as a result of parsing differences between the native and the non-native language. It is then possible that 'parsing' a syntactic structure in the second language is different from 'knowing' that same structure. Consequently, L2 performance may exhibit variation which need not involve incomplete or divergent L2 grammars (Sorace, forthcoming).

Transitivity and argument structure alternations constitute a common research area in language processing. Notice that this area of grammar involves the mapping from lexicon to syntax, and, as such, it requires knowledge of lexical semantics and corresponding syntactic structures. Juffs (1998) found differences in the parsing ability of causative-inchoative alternations in advanced L2 learners of English, who appear to share the same level of grammatical knowledge of these structures in the second language but vary in their ability to parse them. It is argued that the variation attested may be due to the different native languages of the learners (Japanese, Korean, Romance, Chinese) but also to the different rate and pattern of development of the L2 parser compared with the L2 grammar. The discrepancy between L2 competence and L2 parsing has also been found in processing studies concentrating on purely syntactic phenomena, such as wh-interrogatives (Juffs and Harrington, 1995). The claim is that although knowledge of wh-extraction and chain-formation are part of L2 knowledge, L2 learners are sensitive to semantic or pragmatic properties of wh-structures, on-line. Differences between native and non-native language processing have also been identified in relation to 'universal' principles of parsing. The structures involve modification and create local ambiguities of the type *I met the secretary*$_i$ *of the director*$_j$ *who*$_{i/j}$ *was standing on the balcony* (Papadopoulou and Clahsen, 2003; Felser *et al.,* 2003). The prediction for this type of structures is that parsing strategies force the interpretation according to which the person standing on the balcony is the secretary rather than the director. This prediction is not borne out for both native and non-native speakers of English. It is therefore concluded that language-specific parsing preferences together with parsing strategies adopted for non-native language processing need to be taken into account.

Generally, research on language processing focuses on the ability of native and non-native speakers of a language to assign an interpretation to a sentence using lexical or structural knowledge on-line. In a recent study, Papadopoulou and Tsimpli (2004) investigated native and non-native language processing in Greek, focusing on the use of subject-verb agreement morphology to resolve local ambiguities created by optionally transitive verbs. The group of L2 speakers of Greek included participants from different language backgrounds with advanced or near-native knowledge of the language. The results show that whereas native speakers show no significant difference in reading times for the subject and object interpretation, non-native speakers show a significant preference for the object reading, indicating that thematic information, such as transitivity, overrides morphological cues for parsing locally ambiguous structures. Thus, native parsing prioritizes morphology over thematic structure, while the reverse holds for non-native parsing.

Conclusion

Variation in the L2 speaker's linguistic performance is frequently attested. The questions for linguistic theory are whether the attested variation is (a) the result of an underdetermined or incomplete L2 grammar, (b) the result of the 'contact' between the native and the non-native language at the grammar or the interface level, (c) the result of a mismatch between language knowledge and language use, or (d) a combination of these. Research continues to address all of these options as open questions, and fruitful outcome is expected when more is known about mental interaction between the language system, the parser, and higher levels of cognition.

Varma, Siddeshwar (1887–1985)

K Karttunen, University of Helsinki, Helsinki, Finland

© 2006 Elsevier Ltd. All rights reserved.

Born in Rawalpindi in 1887 into a well-to-do Nanda family of the Pañjab, as a son of Rām Dās Nanda and Jamnā Devī, Siddheswar Varma was originally called Piṇḍī Dās Nanda. As a P.W.D. contractor, his father had to move from place to place and thus the son was educated in various schools in Kaimalpur, Gujrat, Rawalpindi, Jhelum, Gujranwala, and Miyanwali (all now in Pakistan). Educated in Urdu, he learned at home, Hindi and Sanskrit. He received a B.A. from Gaudan College in Rawalpindi, then pursued studies at Forman Christian College (of Pañjab University) in Lahore, earning his M.A. in history in 1911.

Varma then worked at Shahpur Durbar as private secretary to the Raja and as tutor of his son. He passed the Shastri examination in Sanskrit in 1913, began teaching, and then in 1915, was appointed Headmaster of Hindu High School in Gujranwala. In the same year, he became Lecturer of Sanskrit at Prince of Wales College (now Gandhi Memorial College) in Jammu. During this time, he worked mainly on Sanskrit and published some text editions. In 1924 he furthered his studies of Sanskrit and linguistics at the School of Oriental Studies in London, earning a doctor of literature in 1927. His dissertation dealt with ancient Indian phonetics, the Prātiśākhya and Śikṣā texts. He also visited Paris and was deeply influenced by J. Bloch. From 1915 to 1943 he taught (first as Lecturer, then Professor of Sanskrit) at Prince of Wales College in Jammu. From Jammu he conducted much fieldwork on languages of Western Himalaya, mostly at his own expense.

During his retirement from 1943 to 1948 he worked at Vishveshwaranand Vedic Institute in Lahore, participating in the preparation of the *Vedic word-concordance*. From 1948 to 1951, he was at the Institute of International Culture in Nagpur, collaborating with Raghu Vira on a Hindi dictionary project. Then, from 1952–1960 he was General Editor in the Central Hindi Directorate, Ministry of Education, Delhi. In 1960 he became head of the Chandigarh Centre of Vishveshwaranand Vedic Institute. He received an honorary doctor of literature from Pañjab University in 1967, and, in 1982, from Jammu University. In his later years he prepared a three-volume summary of G. A. Grierson's large *Linguistic survey of India* (1972–1976) and a series of linguistic analyses of major Indian languages and language groups (1978). Siddheswar Varma died in Delhi on August 18, 1985, at the age of 97.

Varro, Marcus Terentius (116–27 B.C.)

D J Taylor, Lawrence University, Appleton, WI, USA

© 2006 Elsevier Ltd. All rights reserved.

Varro's lengthy life (116–27 B.C.) featured two careers that brought him fortune and fame respectively. During his more than 30 years of military/political activity he served as triumvir capitalis, quaestor, tribune, praetor, and propraetorian legate, was the first Roman to win a *corona rostrata* (or *navalis*), and amassed much wealth and knowledge. He fought with Pompey against Caesar, who pardoned him, but Mark Antony later proscribed him – he escaped, obviously – and destroyed his library. Turning to research, Varro became Rome's most prolific scholar and most authoritative grammarian. A legend in his own lifetime, he was the only living scholar honored with a statue in Rome's first public library, and he has been lavishly praised by Cicero, Quintilian, Augustine, the *grammatici Latini*, the monks of Monte Cassino, Petrarch, Renaissance humanists, and Montaigne, as well as contemporary historians of linguistics, among many others.

Varro was an encyclopedic polymath who authored at least 74 scholarly tomes on subjects as diverse as stagecraft (he determined the genuine plays of Plautus, *inter alia*), numerals, ocean tides, civil law, philosophy, farming, urban affairs, libraries, etc.; his biographical dictionary of 700 famous Greeks and Romans was the first illustrated book, another volume formalized the liberal arts canon, and he composed satires. Varro's first love, however, was language, the Latin language in particular, and he authored at least 10 major works on language science. Unfortunately, only 3% of his voluminous corpus has survived. The losses of the 45 books of the *Antiquitates*, his enthnographical masterpiece, and of all but 6 of the 25 books of his *magnum opus*, the *De Lingua Latina*, are especially regrettable.

In the extant books of the *De Lingua Latina*, Varro etymologizes hundreds of Latin words in the most scientifically rigorous manner possible at the time, but more importantly he discovers, in theory perfectly and in practice almost so, the declensions and conjugations that become the centerpiece of Latin grammar for all time. In the process of that discovery Varro establishes himself as, arguably, classical antiquity's most original linguistic thinker, at least on morphological matters, and sets the agenda for the future of Roman language science. It is therefore no surprise that he is the most frequently cited linguistic authority in the ancient Roman grammatical tradition. The three books of *De Re Rustica*, Varro's only complete extant work, are a literary guide to farming and manifest a genuine affection for land and animals, whereas the 500 or so fragments of his Menippean satires are witty tidbits of philosophical and political insights. Only fragments remain of other works. Nonetheless, Varro is indubitably one of the most prominent figures in Roman intellectual history.

Vasconcellos, Carolina Michaëlis de (1851–1925)

R Cavaliere, Universidade Federal Fluminense, Rio de Janeiro, Brazil

© 2006 Elsevier Ltd. All rights reserved.

Carolina Michaëlis de Vasconcelos built up an impressive academic career as a philologist, ethnographer, and historian of Portuguese literature. Born in Berlin on March 15, 1851, *Dona* Carolina, as she is fondly called in linguistic circles, moved to Oporto, Portugal, in 1876, due to her marriage to the Portuguese writer and art critic Joaquim de Vasconcelos. Her basic education was achieved at home, first with the philogist Eduardo Maetzner and then with the romanist Karl Goldbeck, with whom she studied classic languages. When she was only 16 years old, she set out the paper 'Altspanische Prosadarstellung der Crescentiasage von A. Mussafia' in the pages of the

periodic review *Archiv für das Studium der neueren Sprachen und Litteraturen* (1867); before age 21, she produced a new edition of the *Romancero do Cid* (1871). Nevertheless, one of her more brilliant studies, the edition of *Cancioneiro da Ajuda*, published in Halle (1904), required 27 years of hard and incessant work, as well as another 16 years for framing its glossary (1920). In 1911, *Dona* Carolina was invited to teach at the University of Coimbra and became the first female member of a university institution in Portugal. One year later, she was elected Member Emeritus of the Science Academy of Lisbon.

The contribution of this magnificent scholar to the investigation of medieval and classical Portuguese language and literature is invaluable, which can be easily confirmed by the continuing interest in her texts, still quoted in any contemporary essay on Portuguese philology. This splendid career finished only as a result of her death on November 11, 1925, in Oporto.

Vatican City: Language Situation

A L Lepschy and G Lepschy, University College London, London, UK

© 2006 Elsevier Ltd. All rights reserved.

This article is reproduced from the previous edition, volume 9, p. 4914, © 1994, Elsevier Ltd.

Italian troops entered Rome on September 20, 1870, and Pope Pius IX retired to the Vatican, proclaiming himself a prisoner and refusing to recognize the Italian state. Vatican City was created with the Lateran Pacts of February 11, 1929, which granted the Holy See sovereign jurisdiction over the Vatican. The number of inhabitants in 2002 was ca. 900, of whom half had Vatican citizenship. Italian is the official language of the state, but Latin is the traditional language of the Holy See: it is used in official statements of the Catholic Church and in the Gregorian University. There is also a body of over a hundred Swiss Guards, who are Swiss German speakers. The ecumenical character of the Catholic Church, and the presence of foreign diplomats, contribute to a multilingualism that is considerable in view of the smallness of the state. Pope Karol Wojtyla (John Paul II, 1978–2005) was of Polish mother tongue. His successor, Joseph Ratzinger, 1927– (Benedict XVI, 2005–) is of German mother tongue.

Venezuela: Language Situation

Editorial Team

© 2006 Elsevier Ltd. All rights reserved.

The Bolivarian Republic of Venezuela is located in the north of South America, bordering Columbia in the west, Brazil in the south, and Guyana in the east. In the north Venezuela faces the Caribbean Sea into which the Orinoco River drains. Around 70 islands off the coast belong to Venezuela as well. Venezuela was originally inhabited by several American Indian peoples, including Arawaks, Caribs, and Chibchas. Christopher Columbus established contact with hitherto unknown European communities on his third voyage in 1498. During the middle of the following century, the Spanish established colonial bases along the coast and the adjacent islands, and in 1527 the most important of these, the future Venezuelan capital Caracas, was founded. Colonial rule ended in 1811 and Venezuela became part of Gran Columbia under its first president Simón Bolívar. Bolívar, the Libertador, a native of Caracas, is still held in high esteem in Venezuela today. In 1830, Venezuela separated from Gran Colombia and became an independent republic. The country is very rich in natural resources, including coal, iron, gold, and, above all, oil, and was at one time the world's largest oil exporter. Yet, there are economic problems, including high unemployment and poverty.

The official language of Venezuela is Castilian (Spanish), and is identified as such in the 1999 constitution. The Spanish of Venezuela shares a number of features with other Latin American varieties of Spanish, and more specifically with members of the Caribbean Spanish dialect area. The vast majority of Venezuelans are speakers of Spanish, all official and commercial activities are conducted in Spanish, and the country appears to be linguistically very homogenous. On the other hand, northern South America is one of the most complex linguistic areas of the world, and probably more than 30 Amerindian languages are spoken in Venezuela, almost all of them, however, by very small numbers of speakers. Grimes (2000) lists 40 living languages (see Table 1). Except for Spanish, Venezuelan Sign Language, and Colonia Tovar German (a dialect of German based on the Southern German dialects of migrants in the mid 19th century), these are all Amerindian languages. Most Amerindian languages of Venezuela belong to the Arawakan and Carib families, and the majority of them are spoken by less than 1000 speakers, a significant number by less than 100 speakers. Most Arawakan languages are spoken in the southwest in the border area of Columbia, while Carib languages are spoken in the central and southern parts of the country.

Some Venezuelan languages have further speakers in neighboring countries; for example, Sáliba has 250 speakers in Venezuela, and another 2000 speakers in Columbia, while Nhengatu (Modern or Coastal Tupí) has in addition to 2000 speakers in Venezuela another 6000 speakers in Columbia and Brazil. However, majority of Venezuelan have exceedingly small speaker numbers, and, given that a high proportion of the speaker numbers in Grimes (2000) are based on estimates from the 1970s and 1980s, it is likely that some languages have by now disappeared.

The only Venezuelan Amerindian language with more than 100 000 speakers is Wayuu (Guajiro), spoken on the Guajira Peninsula on the Caribbean

Table 1 Languages of Venezuela[a]

Language name	*Classification*	*Number of speakers*
Arawak	Arawakan	A few
Baniwa	Arawakan	407 (1975)
Baré	Arawakan	A few (1975)
Curripaco	Arawakan	210 (1970)
Guarequena	Arawakan	367
Mandahuaca	Arawakan	3000 (1975)
Paraujano	Arawakan	20 or fewer (1975)
Piapoco	Arawakan	99 (1975)
Wayuu	Arawakan	170 000 (1995)
Arutani	Arutani-Sape	5 (1977)
Sapé	Arutani-Sape	5 (1977)
Akawaio	Carib	A few
Carib	Carib	4000–5000 (1978)
Japrería	Carib	80 (1975)
Macushi	Carib	600
Mapoyo	Carib	2 (1977)
Maquiritari	Carib	4970 (1975)
Panare	Carib	1200
Pemon	Carib	4850
Sikiana	Carib	Possibly none
Yabarana	Carib	20–64
Yukpa	Carib	500
Motilón	Chibchan	850 (1980)
Tunebo, Central	Chibchan	A few
Cuiba	Guahiban	650 (1995)
Guahibo	Guahiban	5000
Piaroa	Salivan	12 000 (1987)
Sáliba	Salivan	250 (1991)
Nhengatu	Tupi-Guarani	2000 (1987)
Ninam	Yanomam	100
Sanumá	Yanomam	1000–4000 (1976)
Yanomamö	Yanomam	12 000–14 000 (1991)
Mutús	Unclassified	200 (1977)
Puinave	Language isolate	240 (1975)
Warao	Language isolate	18 000 (1993)
Yaruro	Unclassified	2000–3000
Yuwana	Unclassified	300 (1970)

[a]Based on Grimes (2000). Number of speakers does not include speakers of the language outside Venezuela.

coast, which has 170 000 speakers in Venezuela, and another 135 000 in Colombia.

Although the constitution identifies the linguistic and cultural rights of the indigenous people, language maintenance and support is not high on the political agenda, partly because fewer than 2% of the population are speakers of an Amerindian language, most of whom live in the more remote parts of the country.

Ventris, Michael (1922–1956)

K A Klar, University of California, Berkeley, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

Michael Ventris was an architect, not a linguist or philologist, by training and usual occupation. He is widely known, however (even outside of the academic world), for a singular linguistic accomplishment, namely, the decipherment of the Mycenaean Linear B script and the determination that the language it encoded was an archaic dialect of Greek.

Ventris first heard of the problem of the undeciphered scripts of the Minoan tablets when, in 1936, as a 14-year-old schoolboy, he heard an impromptu remark by 85-year-old Knossos discoverer Arthur Evans at Burlington House in London to the effect that neither he (Evans) nor anyone else could read the writing on the tablets.

The groundwork had been laid for Ventris' work by a number of scholars, including Emmet Bennett, Jr. and Alice Elizabeth Kober (1906–1950). From Bennett's work, Ventris knew that the Linear B script was likely to be a syllabary. Kober had done preliminary analysis of possible inflectional patterns in the corpus. Ventris, however, in a series of working hypotheses, slowly let patterns emerge and speak for themselves. He never locked himself mentally into one unassailable set of assumptions about the script, but produced a series of visual grids in which he tested hypotheses about the phonetic values of the signs. His 1953 announcement of the successful decipherment caused a sensation in the scholarly world and attracted a large share of criticism, the most vituperative of which came from A. J. Beattie, Professor of Greek at Edinburgh University.

Unlike Champollion's decipherment of Egyptian hieroglyphics, Ventris' work was carried out without the benefit of a parallel inscription for comparison. Ventris' achievement testifies to the importance of intuition and natural ability in linguistic observation and analysis; and in his case, these were coupled with rigorous analytical method and a single-minded dedication to the problem that preoccupied him. Numerous commentators have suggested that his obsession with Linear B and the fame his achievement brought him negatively affected both his personal life and professional (architectural) practice. At his untimely death in an automobile accident on September 5, 1956, he left an extraordinary body of work that any philologist would envy, and yet it centered entirely on the one monumental discovery.

Verbal Conflict

M Jacquemet, University of San Francisco, San Francisco, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

Verbal conflict pervades social life. All around the world, neighbors feud, lovers quarrel, and entire social groups become entangled in wars of words. 'Verbal conflict' can be defined as the open, interactional dispute between two or more parties caused by a clash of goals that the parties perceive to be incompatible. By deploying their verbal skills, the opposing parties seek to gain a dominant position that protects or increases their prestige and secures control over contested resources. Verbal conflict is initiated by the airing of direct or indirect accusations for which speakers must take responsibility, that require opponents to reply, and that cannot be withdrawn without complicated negotiations. Verbal conflict allows speakers to be heard and forces bystanders to take sides. Even as it interrupts the course of social exchange and leads to interactional breakdown or to the destruction of particular relationships, verbal conflict reaffirms the need of social relations and the value of the social group. All societies have developed communicative mechanisms to handle the social aftermath of verbal conflict. From the Trobriander's *yakala* (a session of public insults), to Inuit song duels, to U.S. conflict–mediation sessions, people reenact their conflicts, attempt to reach a solution, and pledge their solidarity to the values and norms of their society. Through communicative performances (both during the conflict and in its aftermath), social networks are activated and social relationships reconfigured. Thus, verbal conflict does not represent a deviation from normal social processes, but rather plays a broad range of functions in constituting social life.

Background

Verbal conflict provides a unique opportunity to study the articulation of language and society. Yet until very recently, we had relatively little knowledge of how people manage conflict in interaction. Most studies of conflict suffered from an absence of detailed primary data, instead electing to present summaries, reports by informants, or reports from meetings held to resolve the conflict. There seem to be several reasons for this lack of data analysis. First, the study of language tended to separate linguistic phenomena from social experience, treating language as part of a scientific system rather than as an activity or practice in the world. As a result, linguistic processes such as verbal conflict were neglected. Even when language was recognized as a form of social action (as in sociolinguistics, speech act theory, or the ethnography of communication), it was analyzed for its conversational coherence and negotiated character, not for it disruptive potential. For instance, researchers concerned with interethnic communication viewed communicative breakdowns as the result of interactants' interpretative failure due to cultural misunderstanding, rather than the intentional outcome of speakers' animosity. Second, as Kulick (1993: 510) pointed out, many verbal conflicts were "often considered to be private, sensitive, and potentially explosive events," thus raising ethical concerns and inhibiting or restricting the collection of material. This may account for the fact that most analyses of verbal conflict dealt with interactions in public settings (such as courtrooms or media events), ritualized performances (such as verbal dueling), or children's arguments. Third, as suggested by Goodwin (1990: 141), researchers may have avoided "studying conflict because it is negatively valued in the white, middle-class society from which the majority of academics are drawn." Since researchers considered conflict a departure from normal social processes, they tended either to ignore it or to concentrate on resolving conflict rather than understanding its linguistic development. Finally, academics' attitudes *vis-à-vis* conflict may have suffered from their cultural gender bias as well: most analyses have focused on verbal competition and conflict as the domain of male speakers, since men are considered to be more verbally aggressive and outspoken, while women were, until recently, believed to be less prone to conflict talk (but see Eder, 1990; Goodwin, 1990; Kulick, 1993, for an opposite view).

To overcome the limitations of earlier research, contemporary work on verbal conflict looks at language as a contested field: a battlefield where interactants (both men and women) are acutely aware of the power of their (and others') words. Researchers in this field now combine concepts developed by interactional sociolinguistics, pragmatics, and conversational analysis (in particular 'speech community,' 'participation framework,' 'sequential organization,' 'pragmatic context') with concepts derived from European social theory articulated by Foucault, Bourdieu, or Williams ('power,' 'ideology,' 'hegemony'). This new brand of conflict research crosspollinates an analysis of language with an analysis of power. Talk is thus analyzed not only for devices that ensure coherence and cohesion, but also for those mechanisms by which speakers/hearers bring about conversational breakdowns and

transform the communicative context. In this light, verbal conflict is understood to be a local technology of power, i.e., a modality for the exercise of power, comprising a whole set of instruments, techniques, procedures, levels of application, and targets.

Strategy

In the study of verbal conflict, we must differentiate between 'discourse strategy' – the overall communicative framework that determines the nature and direction to attain one's objective – and 'tactics' – the detailed verbal and nonverbal moves set up to achieve objectives dictated by strategy. During a verbal conflict, opponents strategize about the best way to establish their position as the stronger, more reliable, and authoritative one, while using specific communicative tactics that seek interactional, turn-by-turn dominance.

The overall strategy of verbal antagonists deals with the representation of their social relationship, as it is indexed in their communicative practices. Disputants deploy strategies that endow them with better opportunities to talk, establish certain regions of knowledge as authentic and meaningful at the expense of others (usually endorsed by the opponent), and link this authenticity to systems of power that can boost their claims to credibility. Moreover, they increase their credibility through their ability to evoke and use relevant domains of knowledge, and by clashing over the rules, conditions, and procedures that establish what is believed to be true and what is believed to be false (see Bourdieu, 1991). In particular, speakers seek to establish themselves as having higher standing than their opponents as the preliminary move to claim authority for their words. For instance, in Tanna, Vanuatu, during verbal conflict people routinely claim to be "big men" that therefore "must be listened to" and "believed" (Lindstrom, 1992); similarly in southern Italy, opponents seek the status of "man of honor" as a position from which to "speak the truth" (Jacquemet, 1996). In more general terms, people deploy their accent, technical vocabulary, or communicative demeanor as indexes of their superior social standing – a metonymic indicator of the superiority of their argument over that of the opponent.

Ruling elites and people in position of authority seem to be better placed to take advantage of their superior status to claim credibility for their words. However, authority does not translate directly into performance, since one's dominant social position must still be enacted in talk. The more powerful and authoritative a speaker is, the better are his or her chances of influencing the outcome of the conflict, but this outcome cannot be taken for granted: it is ultimately decided by their communicative performance. In the give-and-take stream of talk that characterizes verbal conflicts, the structurally 'weaker' but communicatively better equipped participant could shape the local development of the interaction in such a way as to neutralize the possibility that the 'stronger' party would resort to extra-communicative means to achieve his or her agenda (such as using violence or appealing to powerful social connections).

Verbal conflict acquires an extra dimension when it occurs in public. The presence of a third party – an audience – seriously impacts the development and outcome of the verbal conflict and is considered by most researchers as a necessary element for conflict resolution. Moreover, verbal conflicts play a crucial role in publicizing and condemning social violations. As early as the first decades of the 20th century, Malinowski highlighted the social-control function of public verbal conflicts. In his study of the Trobrianders' laws and customs, he argued that incest and other forbidden behaviors came to be viewed as crimes only when they became public through verbal conflict. In discussing an incest case, he observed that "public opinion was neither outraged by the knowledge of the crime to any extent, nor did it react directly – it had to be mobilized by a public statement of the crime and by insults being hurled at the culprit by an interested party" (1926: 79). In contrast to gossip, which transmits its messages along a one-to-one line and is thus subjected to serious noise distortion, the *yakala,* or public expostulation, broadcasts its message over an open field to the entire audience. Such speech has clear originator and target and reaches everyone within earshot, and its value-heavy content assures that it cannot be dismissed as idle talk or ignored all together. Verbal conflicts force the audience to act to try to restore the social order disrupted by the conflict.

The presence of an audience during verbal conflict forces the opponents to engage in various strategies to gain the audience's support. Even if an imbalance exists in instituted authority or social power, successful performances will depend upon the participants' ability to modify the contextual frame of the exchange (i.e., the relative positions/roles/attitudes of the participants in the interaction) by setting up the conditions that would allow one's argument to be heard. In particular, to capture the audience's support, speakers attempt to frame their arguments as embodiments of shared beliefs and understandings. Such framing is a primary strategy by which individuals and groups attempt to legitimize their perspectives. As Brenneis (1988: 227) argues, verbal conflicts create accounts of disputed incidents, where "the effectiveness of these

accounts depends in large part upon the degree to which they meet audience expectations of sensibleness, appropriateness, and good form." In a similar vein, Goodwin (1990) studied telling stories about an antagonist as one of the most successful strategies for restructuring the social organization of an ongoing conflict, transforming passive overhearers of the conflict into active participants, and thus altering the 'participation framework' (i.e., the ensemble of interactive roles potentially available to participants in the speech event). The creation of an account that is detrimental to the opponent not only avoids unilateral exits or direct replies from the antagonist (always an option in the back-and-forth format of accusations and counters typical of a verbal conflict), but since it is directed to all participants, it also allows the creation of power alliances between the storyteller and other participants, who are drawn into the conflict by the compelling power of the story.

The narrative dimension of verbal conflict involves two levels of possible dispute: the speaker's act of saying something reprehensible and/or inflammatory, and the actual report about the opponent's reprehensible and/or objectionable acts. This tension between narrative performance and narrated event brings to the fore the relationship between the pragmatic and the referential dimensions of a verbal conflict. As Irvine (1992) queried, "is the narration perceived as more inflammatory than the narrated event, or vice versa? And if the violation is present in both, which is to be taken more seriously?" These questions point to the varieties of contexts (cultural, linguistic, and situational) that different communities take into account in their handling of verbal conflicts. For instance, some communities (such as the working-class white communities in the Carolina Piedmont studied by Heath, 1983) are mostly concerned with narrated events, while others (such as the African–American groups studied by Abrahams, 1963; Labov, 1972) focus on the narrative performance. Discourse strategies in verbal conflicts are therefore tailored to a particular community's primary focus: in the former, the issues of representation, accountability, and responsibility come to the foreground, while in the latter, emphasis is placed on verbal skills, inventive counters, and quick delivery.

Tactics

While verbal opponents rely on discourse strategies for the overall plan of their dispute, various verbal tactics are deployed throughout the sparring of the battle. Among the many techno-political devices employed on this level, special attention has been recently given to speech moves able to elicit particular responses or establish new conditions for the reception of the conflict. In particular, from public debates to institutional fights to private squabbles, researchers have been focusing on the disruptive but empowering quality of direct speech ('straight talk') associated with verbal conflict. Three such devices of primary importance are 'contextualization tactics,' 'recourse to metapragmatic statements,' and 'tactical use of insults.'

'Contextualization tactics' are communicative practices that both produce representations of the social world in accord with a given ideology and seek to persuade others to comply with these representations. Such tactics are found in all societies and usually consist of three parts: the decontextualization of an event from its occurrence in a particular space and time, its entextualization into a discourse with a more controllable set of truth values, and the recontextualization of this discourse within a communicative frame set up to legitimize it (see Bauman and Briggs, 1990; Silverstein and Urban, 1996). For instance, the speaker may elect to embed an opponent's statement within his or her own speech while inverting its referential value or adding a negative comment through intonational coloring. Most instances of reported speech in argumentative situations conform to this tactic: the embedded segment, which usually takes the form of a short quotation from the opponent's previous talk, serves the speaker in the unflattering representation of the opponent, in its representation of the relationship between the two sparring partners, and through the cues it presents to the audience about how to read the conflict.

Secondly, the 'recourse to metapragmatic statements' (i.e., statements about the implicit social meaning conveyed by speech) is triggered by speaker's awareness of how speech forms are used to establish the indexical relationship between interactants: the speaker's stance or attitudes *vis-à-vis* the opponent (one-up/one-down); the social relations or relative status of the participants; and special attributes of particular individuals (see Silverstein, 1976). In verbal conflict, participants usually are keenly aware of the specific use of signs that refer to the conflict at hand, whether this use involves reference to specific words used by the opponent, or to particular instances of speech (the opponent's style of delivery, intonation, or underlying logic). In these cases, metapragmatic awareness turns vicious and manifests itself in a "meta-pragmatic attack" (Jacquemet, 1994): a strategy of consciously and overtly calling attention to and/or mocking the opponent's performance for the purpose of interactional control. A metapragmatic attack can be used to comment on nonverbal behavior ("don't use that tone with me"), to draw attention

to a particular word or style ("don't call me stupid," "you sound like a broken record"), or to address the indexical relationship between speaker and hearer ("you don't know who[m] you're talking to" or "you must call me 'sir'"). An explicit accusation at the metapragmatic level produces a communicative break that escalates the stakes of the conflict. A metapragmatic attack puts an opponent on the defensive, without the speaker having to level any specific accusations, and challenges the opponent to address the attack at the metapragmatic level. This interactional escalation can produce verbal sequences called 'format tying,' a subtle but significant transformation of an utterance in which the speaker repeats what the opponent has just said, but changes it minimally to highlight opposition (A: "I don't know what you laughin' at"; B: "I know what I'm laughin' at. Your head" see Goodwin, 1990: 177). Metapragmatic attacks unravel the raw fabric of communicative interactions, exposing the disputants' maneuvers as they struggle for control, respect, and interactional dominance.

Finally, most verbal conflicts rely on insults to achieve their communicative effect. Leach (1964: 28) suggested that the language of abuse falls roughly into three categories: "(1) 'dirty words,' usually referring to sex and excretion; (2) blasphemy and profanity; and (3) animal abuse – in which a human being is equated with an animal of another species." These types, according to Leach, are found in most cultures around the world. They are indeed well represented in verbal conflicts, where they may play a crucial role in escalating the intensity of the exchange. Kulick (1993) highlighted three functions of insults: they draw the opponent into open warfare; they create an awkward and embarrassing situation for all present, thus implicating the opponent in this social gaffe; and they are tactically deployed at points in the conflict where closure or negotiations seem possible, allowing the insult-giver to maintain control over the sequential organization of the conflict, and in particular over its resolution. However, as Irvine (1992) pointed out, how a particular expression counts as an insult or as verbal abuse is quite problematic, requiring a great deal of contextual, cultural, and situational knowledge. Many innocuous statements can be turned into abusive ones, depending on the context to which they refer and on their position within the stream of talk. As Irvine (1992: 110) stated:

> Insults are not simply a set of statements, or a type of content inherent in statements. Instead, insult is a communicative effect constructed in interaction – constructed out of the interplay of linguistic and social features, where the propositional content of an utterance is only one such feature [...]. Conceivably anyutterance, or even silence, could have the perlocutionary effect of insult if enough interactional features suggesting it are brought into play.

Verbal abuse is grounded in specific cultural systems of moral judgment, and as such, it must be investigated by exploring how the dominant norms and values of a given society are invoked in specific interactional events.

Verbal Duels

A special case of verbal conflict concerns the widespread communicative practice of verbal dueling: the competitive exchange of usually obscene insults and invectives between at least two parties. This exchange is performed in a highly ritualized and codified space, in which participants can avoid the contest's potential to unleash social disruption. In this public space, two or more duelists with narrowly circumscribed roles and tasks are asked to match their linguistic skills in front of an audience, which selects the winner based on socially shared criteria of what constitutes a winning performance.

In most cases, verbal duels are used as conflict-resolution devices, resulting in the public rebalancing of the wills and reputations of the duelists, thus ensuring their good relations in the future. For instance, in the Inuit duels studied by Hoebel (1954), conflicts in the community were reduced through two forms of regulated combats: wrestling and song duels (sometimes in association with head butting). The duel must, however, maintain a symbolic distance from the real conflict and should not provide a factual representation of the conflict. Through the duel, the conflict was moved to a symbolic space and separated from everyday life. In this symbolic space, verbal duels created an overriding sense of solidarity among players. This led to a harmonious resolution of the initial conflict, marked by a common meal.

It is the rule-governed nature of the exchange that maintains the symbolic distance between the verbal duel and serious conflict. All the major elements of a duel (the time allotted to each duelist, the shape and content of their lines, the conservation of form and content across participants' turns, the audience response) are strictly regulated and enforced, marking the controlled nature of the event. Adherence to strict rules shields both performers and audience from the dangers usually associated with verbal conflict. In particular, participants need not worry about producing truthful statements, and in many settings, content must be obviously fictional (for instance,

during African–American sounding games, any insult too close to reality is negatively received by the audience and may trigger a serious confrontation; see Labov, 1972). Likewise, performers are expected not to take issue with the opponent's remarks and must not show the anger or embarrassment usually caused by an opponent's accusations.

Verbal duels are widely scattered around the world; they have been reported from the Mediterranean area (Malta, Turkey, Sardinia) to the Americas (Mexico, the Caribbean, the United States), from Africa (Tiv, Yoruba, Efik) to the South Pacific (Fiji). In most cases, participation is reserved for male performers, while women may be in the audience. To date the ethnographic evidence of women involved in ritual insults centers on the life-transition occasion of the wedding. The most thoroughly documented case of women performers is Irvine's study (1992, 1996) of *xaxaar*, a Wolof insult poetry event in which a bride's prospective cowives hire women of lower rank, usually griot women, to recite poems vilifying the bride.

The basic distinction among (male) verbal duels is between adolescent games and adult contests. Adolescent games adhere to specific stylistic shapes of challenge and retort, in which individual performances depend on creativity and especially on the mastery of a traditional repertoire of statements. These duels are typically concerned with forcing and/or depicting the opponent in a passive role, and content is heavily composed of references to alleged homosexual (bottom) behavior (see, among many, Abrahams, 1962; Labov, 1972; Dundes *et al.*, 1970; Gossen, 1976). On the other hand, adult contests are stylistically more demanding: participants' turns are longer and more complex, insults are often sung rather than spoken, and sometimes a single topic is set in advance either by the first performer or by the organizers or audience of the duel.

Both kinds of verbal duels undergo a collective process of evaluation by the audience, which in most cases decides (either explicitly or through applause and comments) the winner. In cases in which the verbal duel has been organized to settle a real-world dispute, the jury concerns itself more with re-establishing harmony in the community than with determining guilt or innocence. In a number of cases found in the literature, the audience/jury usually declares one party the winner of the contest, but adjudicates in favor of the other, thus reaching a settlement where both parties 'win.' In other cases, especially with adolescent duels, losers are usually those unable to come up with a witty counter: "There is always a winner, he who says the last word, and a loser, he who cannot answer the challenge" (Gossen, 1976: 126).

Ritual Wailing

While verbal duels are almost exclusively a male domain, 'ritual wailing' – the communicative practice of publicly, collectively, and loudly expressing grief, sorrow, or anger for the death of a dear one – is a female domain. Where a verbal duel may function as an attempt at reconciliation between feuding parties, ritual wailing can be functionally understood as the attempt to atone for a different kind of communal conflict: the breakdown and disruption caused by the loss of a group's member. Many researchers have characterized these performances as a form of resistance in which women can express open criticism of their community and verbally abuse other members. Ritual wailing operates with the basic mechanism of verbal conflict: a wailing woman, using her sorrow as a backdrop, can safely insult individuals or groups she does not like or she reputes to be in violation of social obligations (Knudsen, 1988; Seremetakis, 1991; Briggs, 1992; Urban, 1988). As such, ritual wailing can be seen as a powerful device for social defiance and, at times, can have a powerful impact in determining the policies and decisions of a community.

Ritual wailing shares with verbal duels many communicative features: the presence of a public audience (at times quite large), the focus on the performative moment, the use of formulaic speech, and the reliance on metapragmatic devices (in particular, reported speech; see Briggs, 1992). During ritual wailing, the voices of many women not only express emotions but also deliver strong public statements about the reasons behind the death, the ensuing imbalance caused by it, and the steps needed to recover a communal equilibrium. For instance, Knudsen (1988) reported that ritual wailings played a central role in the *vendetta* tradition in Corsica during the 18th and 19th centuries, where women called out the names of male relatives charged with the task of avenging the death, using derogatory language to prompt them into action.

On the other hand, women may also elect to use the wailing performance to present other women in a particular unfavorable light or to insult them directly. The accused women will then be forced to respond by entering this performative space. For instance, Seremetakis (1992) documents the clash between a grieving mother and a former friend of her dead son, in which the latter strenuously fought in her lament to represent her relationship with the deceased as casual, thus shielding her from the strict code of mourning a relative.

Through the high voicing of the laments, women represent the violence of death through language and sound – the acoustic pain of day-long singing screams

metaphorically evoking this violence and its underlying conflict. Through their emotional, supposedly out-of-control outburst, they impose decisions on the entire community by producing statements that appeal to collectively held moral obligations. For instance, in their laments, the Warao women of Venezuela appropriate and recontextualize words initially used in settings where only men are accorded a voice, and in so doing they act to restrain the authority of male shamans and political leaders: "Women (and women alone) are accorded the right to criticize whatever and whomever they please through songs following a death" (Briggs, 1992: 347).

The communicative force of the laments rests once again on the fact that these words have been uttered in a public space: wailers acquire the power to command an audience and put on record their assessment of the community, thus forcing their discourse into the public sphere – in most cases without the possibility of a rebuttal. As death becomes the last chapter in the life of an individual, death laments are the 'last words' (Seremetakis, 1992) through which women can rewrite biographies, shuffle group histories, and propose new sets of norms and values.

Conclusions

From the study of verbal conflict, we can draw some broader conclusions about the relationship between language and society.

First, we see that most linguistic techno-political devices (such as reported speech or metapragmatic attacks) are always (that is, not only in verbal conflict) intentionally staged, performative acts. All speakers, including those in positions of dominance, need to perform their power: they stage these acts to express their will to power. Most dominant classes can, however, count on some helpful aids, such as a dilution of responsibility (such as the Wolof practice of paying a griot to speak instead of a noble [Irvine, 1992]) or the 'plausible deniability' sought by high public officials. In the process of this performance, the relative power of each interactant is put to the test. Thus, the outcome of any attempt to gain control over communicative resources is never predetermined; power in interaction (especially during verbal conflict) must be claimed through the use of communicative resources – asymmetrically distributed but always negotiable in performances.

Second, verbal conflict teaches us to avoid a simplistic correlation between speech forms and power; its techno-political devices are deployed from all positions, from the core as well as from the periphery, from the superior as well as from the inferior. Different forms of domination produce different configurations of language use. Any particular linguistic form gains different meanings and has different social and political effects as a function of specific institutional and ideological contexts.

Third, verbal conflict, because it calls extraordinary attention to the spoken word, generates frequent instances of communication as verbal hygiene. In these instances, disputants produce correct, clean forms of talk-linguistic techno-political devices that, in order to be effective, invoke particular assumptions about standard language, proper talk, and normative behavior. Through verbal hygiene, disputants attempt to demonstrate their solidarity with the norms and forms of the community (actual or imagined) to which they are appealing for support.

Finally, verbal conflict forces us to address the issue of the relationship between language and social change. Battles over language use (as they are evoked and transformed during a conflict) change the repertoire of social meanings associated with power relations. Through verbal conflict, social indexicalities are interactionally transformed, opening the way for more profound social transformations. The struggle over the sexist bias of the English language (evidenced, for instance, in the unmarked nature of the generic masculine pronoun) provides an example of this potential for change; linguistic awareness of gender bias has rendered problematic the generic use of the masculine pronoun, and this newly produced sensitivity can be exploited during a verbal conflict, since a speaker could metapragmatically point out the 'politically incorrect' use of a gendered form. It would be naive to claim that awareness of sexist language and its recourse during verbal conflicts change gender relations. However, by focusing speakers' attention on the inner workings of language, conflict opens a reflection on the social meanings of particular linguistic repertoires, and this in turn can lead to structural change.

Verbal Hygiene

D Cameron, Institute of Education, London, UK

© 2006 Elsevier Ltd. All rights reserved.

This article is reproduced from the Concise Encyclopedia of Sociolinguistics, pp. 688–690, © 2001, Elsevier Ltd.

It is a truism that linguistics is 'descriptive not prescriptive' – concerned to describe the structure and use of natural languages, and not to make value-judgements on them. *Verbal hygiene* was the title of a book that prompted debate among sociolinguists, by challenging the view that value judgements are of no relevance for linguistics (Cameron, 1995). It argued that competent language users routinely make value judgements on language; ideas about what is 'good' and 'bad' in language are central to their understanding of it, and ought therefore to be of interest to linguists who study language use as a form of social behavior.

What is Verbal Hygiene?

The importance language users accord to value judgements is seen with particular clarity in practices of 'verbal hygiene,' i.e., active attempts to improve or 'clean up' language. These practices are many and varied. Examples include not only efforts to impose a standard dialect, pronunciation, or spelling, but also cases like plain-language movements or feminist campaigns to eliminate sexist language, language planning, and 'fringe' movements advocating wholesale spelling reform, the abolition of copular verbs, or the adoption of artificial languages. What these instances have in common is not any single view of what is desirable in language use – the traditional grammarian and the feminist, for instance, will disagree on many points of detail. But they do share the more fundamental assumption that one way of using language may reasonably be preferred to another.

Verbal Hygiene and Prescriptivism

That assumption also underlies what linguists have traditionally called 'prescriptivism': how does 'verbal hygiene' differ? Cameron (1995: 3–11) saw the two concepts as overlapping but not coextensive. Her main reasons for wanting an alternative to 'prescriptivism' have to do with the meanings that term has acquired in linguists' usage. First, 'prescriptivism' is most closely identified with a particular subset of normative metalinguistic practices, those that focus on the value of **correctness** and equate 'correct' usage with adherence to the codified norms of a standard language variety. The term 'verbal hygiene' seeks to foreground the existence of normative metalinguistic practices, which intervene in language use in different ways and for different reasons, though they are equally animated by value judgements. Secondly, 'prescriptivism' in linguistics has acquired strong negative connotations: it is associated with ignorance, intolerance, and prejudice, and is usually represented as something extraneous to normal language use. Verbal hygiene, by contrast, is presented as part of a more general metalinguistic function, which is integral to the workings of verbal communication:

> Because language-using is paradigmatically a social, public act, [it] must be carried on with reference to norms, which may themselves become the subject of overt comment and debate. In our everyday interactions we take this for granted ... without recourse to such ordinary metalinguistic practices as correcting slips of the tongue, asking what someone meant by something or disputing their usage of particular words, the enterprise of communication would be even more fraught with difficulty than it already is (Cameron, 1995: 2).

From this point of view, it makes no sense to condemn linguistic normativity as such. Further, when one considers the full range of normative practices language users are engaged in, it becomes difficult to argue that they all exemplify ignorance (cf. language planning, a 'scientific' enterprise) and/or prejudice (cf. campaigns against sexist and racist language, which embody **resistance** to certain forms of prejudice). While verbal hygiene practices are never value-free, 'correctness' is not the only value that informs them. Others include esthetics (as in discussions of why one local accent is preferable to another); utility (as in arguments for official documents to be written in plain language rather than obfuscatory jargon); and morality (as in debates on sexism and racism in language).

The Social/Symbolic Functions of Verbal Hygiene

Although verbal hygiene arises from a metalinguistic capacity that is indispensable for communication, in practice that capacity is used in ways that go well beyond immediate communicative needs – clearly we do not 'need' new spelling systems or arguments about how best to translate the Bible into Klingon (the invented language of a fictional alien species). Many verbal hygiene practices are better understood in terms of the social and symbolic purposes they serve for those engaged in them.

In some cases, these purposes are broadly political: verbal hygiene is used to affirm a particular view of the ideal social order. This motivation is evident in conservative defences of standard languages, in feminist arguments for nonsexist language and the counterarguments of their opponents, in purist movements to purge languages of 'foreign' elements, and in attempts to preserve or revive minority languages as symbols of ethnic or national identity. Professional and commercial interests (e.g., the interest of publishers in maintaining certain norms of written style) may also motivate verbal hygiene. And it can also be a form of 'language play' (Cook, 2000) – this function is probably its main one for Klingon enthusiasts, for instance.

Debates on Verbal Hygiene

Some linguists (e.g., Kalogjera, 2000) have criticized verbal hygiene as a 'revisionist' concept that rehabilitates reactionary forms of prescriptivism, undermines the objectivity of scholarship, and encourages sociolinguists to politicize discussions of language attitudes and linguistic change. In *Verbal hygiene* (Cameron, 1995: xi) it is noted that linguists can study normative practices without necessarily endorsing them. However, the book does challenge claims that linguistics itself is value free (the axiom 'all varieties are linguistically equal,' for instance, is not just a statement of what linguists believe to be true, but implicitly also a value judgement). If we accept that evaluation and verbal hygiene are integral parts of language-using, sociolinguists must engage in critical debates about the **grounds** for particular evaluations rather than denying the legitimacy of evaluation itself.

Verbs

Å Viberg, University of Uppsala, Uppsala, Sweden

© 2006 Elsevier Ltd. All rights reserved.

Verbs vs. Nouns

Verbs and nouns are the two major word classes in most, possibly all, languages (*see* **Word Classes/Parts of Speech: Overview**). With respect to meaning, basic concrete nouns tend to follow perceptually salient natural partitions in human environment according to the natural partitioning hypothesis (Gentner and Boroditsky, 2001), whereas verbs to a greater extent are language-specific and show greater variation with respect to meaning across languages. This feature explains why children universally tend to acquire early nouns before early verbs.

The verb is the core of the clause and has a relational meaning, relating to one or more participants (or arguments) to an event. In general, verbs are more complex than nouns and tend to represent a greater cognitive load on processing than nouns. Another basic characteristic of prototypical verbs is that they crucially involve change through time, whereas concrete nouns tend to be stable across time.

Lexicalization Patterns

Verbs are primarily used to talk about events, but the way events are encoded may vary dramatically. In Kalam, a language spoken in the highlands of Papua New Guinea, many events that are encoded as simple verbs in English are described as a sequence of events, each encoded by a simple verb (Pawley, 1987):

(1) Kab añañ ap yap pk-e-k pag-p ok.
stone glass come fall it-having-hit-DS it-has-broken that
A stone broke the glass.

Kalam is a good example of a verb serializing language (*see* **Serial Verb Constructions**). Serial verbs exist marginally in English, in sequences such as *Go get the book*. Serial verbs are, however, characteristic of Southeast Asian, West African, Papuan, and Oceanic languages (Crowley, 2002). Verb serialization is defined as a combination within the same simple clause of lexical verbs that can function independently as verbs and that must be interpreted as having the same values for tense-aspect-mood even if those values are not necessarily overtly marked on all of the verbs in the series. Auxiliaries (or helping verbs)

In some cases, these purposes are broadly political: verbal hygiene is used to affirm a particular view of the ideal social order. This motivation is evident in conservative defences of standard languages, in feminist arguments for nonsexist language and the counterarguments of their opponents, in purist movements to purge languages of 'foreign' elements, and in attempts to preserve or revive minority languages as symbols of ethnic or national identity. Professional and commercial interests (e.g., the interest of publishers in maintaining certain norms of written style) may also motivate verbal hygiene. And it can also be a form of 'language play' (Cook, 2000) – this function is probably its main one for Klingon enthusiasts, for instance.

Debates on Verbal Hygiene

In general, verbs are more complex than nouns and tend to represent a greater cognitive load on processing than nouns. Another basic characteristic of prototypical verbs is that they crucially involve change through time, whereas concrete nouns tend to be stable across time.

Lexicalization Patterns

Verbs are primarily used to talk about events, but the way events are encoded may vary dramatically. In Kalam, a language spoken in the highlands of Papua New Guinea, many events that are encoded as simple verbs in English are described as a sequence of events, each encoded by a simple verb (Pawley, 1987):

(1) Kab añañ ap yap pk-e-k pag-p ok.
stone glass come fall it-having-hit-DS it-has-broken that
A stone broke the glass.

Kalam is a good example of a verb serializing language (*see* **Serial Verb Constructions**). Serial verbs exist marginally in English, in sequences such as *Go get the book*. Serial verbs are, however, characteristic of Southeast Asian, West African, Papuan, and Oceanic languages (Crowley, 2002). Verb serialization is defined as a combination within the same simple clause of lexical verbs that can function independently as verbs and that must be interpreted as having the same values for tense-aspect-mood even if those values are not necessarily overtly marked on all of the verbs in the series. Auxiliaries (or helping verbs)

also appear in sequences of two or more verbs such as *Mary should have come*, but such sequences are introduced by an auxiliary in finite form followed by one or more verbs in various nonfinite forms.

Kalam is also a good illustration that the number of verbs can vary dramatically. In this language, around 15 simple verbs account for close to 90% of the occurrences of verbs in running text, and the total number of simple verbs is around 100. In English and other European languages, there are something in the range of 10 000 different verbs or more. The frequency of occurrence, however, singles out a small number of verbs as basic even in European languages. The 20 most frequent verbs tend to cover close to 50% of the textual frequency of verbs in representative corpora. Among them are several verbs with predominantly grammatical functions such as the copula *be*, the verb *have*, and modal verbs. But in addition, there are a number of lexical verbs referred to as nuclear verbs in Viberg (1993) that tend to be the most frequent verbs within the most basic lexical semantic fields (or conceptual domains) such as motion (*go/come*), possession (*give/take*), production (*make*), verbal communication (*say*) and perception (*see*). The nuclear verbs tend to be basic even in non-European languages. Even if verbs are more language-specific than nouns, this characteristic is only a matter of degree.

Nuclear verbs also tend to have a rich pattern of polysemy. Newman (1996, 1998) demonstrates this pattern for the verb *give* across a wide range of languages, showing a strong crosslinguistic tendency for verbs with this meaning to extend into the grammatical areas of recipient/benefactive, permission/enablement, and causation. It has also been possible to show that basic meanings within a field are lexicalized in a certain order across languages. For perception, there is a hierarchy: see > hear > feel/taste/smell. Verbs of perception have a tendency to extend their meaning to cover cognitive meanings such as *understand* and *know* (Viberg, 1984, 2001; Evans and Wilkins, 2000). From another perspective, a number of studies based on Talmy (1985, 2000) have looked at conflation patterns, the way meaning components are combined ('conflated') to form the meaning of verb roots, in particular, how motion verbs across languages can combine motion + Path (*enter, descend*) or motion + Manner (*run, swim*). Originally, Talmy divided languages into two major types depending on what alternative was dominant, but more recent research has come to regard this evidence as a continuum where languages, for example, can be placed along a cline of manner salience (Slobin, 2004).

The semantic organization of the more or less complete set of verbs in a language can be described in WordNet format, based on semantic relations such as hyponymy, antonymy, and synonymy. (See Fellbaum, 1998 for English, Vossen, 1999 for other European languages. See also Relevant Websites at the end of this article.) (*see* **WordNet(s)**.)

From Semantic Representation to Syntactic Argument Structure

As mentioned, verbs are relational, and an essential part of the meaning of a verb is the type of relations it holds to various arguments, the argument structure (*see* **Argument Structure**), in particular subjects and objects such as *man* and *car* in *The man washed the car*. According to the approach to semantics known as frame semantics (*see* **Frame Semantics**), verbs (and other relational words) evoke frames – schematic structures of recurring situations. A verb such as *give*, for example, evokes the transfer frame, which can be described as follows: Someone (the Donor) is in possession of something (the Theme) and then causes someone else (the Recipient) to be in possession of the Theme. This frame is evoked by *give* in sentences such as: *The teacher* (Donor) gave *the student* (Recipient) *a book* (Theme) or alternatively: *The teacher* (Donor) gave *the book* (Theme) *to the student* (Recipient). The syntactic realization of the frame elements can be described with respect to Phrase types (NP, PP, etc.) and grammatical functions (subject, object, complement, etc.) in Table 1.

See Fillmore *et al.* (2003) for a description of the large FrameNet lexical database of English, containing verbs and other abstract words organized according to these principles. At the time of writing, there are more than 200 frame elements, but many of them are hierarchically related to more general frame elements. For example, Donor is a type of Agent.

Verbal Morphology

Morphological markers on the verb are primarily of three types: Valency markers, Agreement/Reference markers, and Tense-Mood-Aspect (TMA) markers. The number of inflectional markers on the verb varies

Table 1 Schematic structure of a sample sentence, using the verb 'give'

	The teacher	*gave*	*a book*	*to the student*
Frame elements	Donor		Theme	Recipient
Phrase types	NP		NP	PP-to
Grammatical functions	Subject		Object	Complement

dramatically across languages from zero to several hundred. However, the inflectional categories that exist primarily belong to a restricted number of major categories with a few central members. The inflectional markers have a characteristic order according to their decreasing relevance to the meaning of the verb (Bybee, 1985): Aspect occurs closest to the stem, followed by tense, and then by mood, which is followed by person.

Even if the arguments of verbs can appear in a wide range of phrase types and grammatical functions, there is a core consisting of subject and object and (in some languages) indirect object that is central in grammatical descriptions of clause structure. Valency refers to the number of core arguments. Among derivational processes characteristic of verbs, valency-changing derivations hold a prominent position (Dixon and Aikhenvald, 2000). Such derivations are basically of two types as shown below:

- Decreasing: Passive, Antipassive, Reflexive, Reciprocal, Anticausative (and Middle, which is problematic)
- Increasing: Causative and Applicative

The terms mentioned above should be reserved for constructions containing some type of explicit formal marking. Languages can also have a number of **ambitransitive verbs** that can be either transitive or intransitive without any derivational marking such as English *melt* (*John melted the lead* vs. *The lead melted*).

In many languages, certain semantic features of the arguments of the verb are signaled by morphological markers on the verb, a phenomenon known as verbal agreement (Barlow and Ferguson, 1988). There is a formal and a functional view on agreement. The markers can be regarded as redundant copies of information already present in the clause, a view that is most natural when the argument must also be present as a free word such as the English 'third person singular –*s*': *He/She knows*. In some languages, however, verbal agreement markers in many clauses are the only explicit markers of the referents of the core arguments of the verb and anaphoric pronouns in the form of independent words are primarily used for various types of emphasis. Because of this incidence, functionalists often refer to verbal agreement as reference tracking, i.e., indexing on the verb of its arguments by various morphological means, and it might be argued that even redundant markers, such as in English, serve as cues for the interpretation together with more explicit cues. The semantic features that are marked on the verb by verbal agreement are (a subset of) the ones that are characteristic of anaphoric pronouns, such as person, number, and (to a lesser degree) gender or noun class. Usually agreement arises from grammaticalization of anaphoric pronouns, but other sources such as analogy exist. The most commonly marked argument is the subject, but it is not uncommon for languages also to mark the object on the verb. There are even languages that mark the indirect object or (in a few languages) some oblique function. Languages that completely lack verbal agreement are also common. Referential tracking can be achieved also with switch-reference markers on a medial verb in a serial verb construction or a verb in a subordinate clause indicating whether its subject is identical with (same-subject: SS) or different from another verb (different-subject: DS. See the example from Kalam above) (*see* **Switch Reference**).

The inflection of tense, mood, and aspect that is also highly characteristic of the verb is treated in a separate article (*see* **Tense, Mood, Aspect: Overview**).

Verificationism

M Beaney, University of York, York, UK

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Verificationism is the view that the meaning of a (synthetic or empirical) statement is given by its method of verification. A sentence, as used on a given occasion to make a (synthetic or empirical) statement, has meaning if and only if its truth or falsity can – in principle – be determined by experience. Verificationism was the central doctrine of logical positivism (also called 'logical empiricism'), a movement that originated in the work of the Vienna circle in the early 1930s and received its classic statement in A. J. Ayer's *Language, truth and logic* (1936). Although subject to devastating criticism in the 1940s and 1950s, the motivation behind verificationism has continued to influence philosophers ever since, most notably, in the work of W. V. O. Quine and Michael Dummett. Indeed, the basic positivist impulse – to reject anything that is not grounded in sensory experience – goes back at least to David Hume, and has been a significant feature of the philosophical landscape throughout the modern era. Hume's famous words at the very end of his *Enquiry concerning human understanding* are often taken as the definitive statement of the underlying positivist view:

> If we take in our hand any volume; of divinity or school metaphysics, for instance; let us ask, *Does it contain any abstract reasoning concerning quantity or number?* No. *Does it contain any experimental reasoning concerning matter of fact and existence?* No. Commit it then to the flames: for it can contain nothing but sophistry and illusion.

The repudiation of metaphysics was characteristic of logical positivism, too, and this was rooted in the doctrine of verificationism.

The Analytic/Synthetic Distinction

Central to logical positivism was the distinction between analytic and synthetic statements – corresponding to Hume's distinction (implicit in the passage just quoted) between relations of ideas and matters of fact. According to the logical positivists, a statement is analytic if and only if its truth or falsity is determined solely by the meaning of its constituent terms. 'All bachelors are unmarried men,' for example, was seen as true in virtue of the meaning of the term 'bachelor.' Analytic truths were regarded as both necessary and *a priori*. Their necessity was seen to lie in their tautological nature, a view that the logical positivists took from Ludwig Wittgenstein. Since, on their account, analytic truths could be judged to be true merely by knowing their meaning – without needing to consult the world in any way – they were also regarded as *a priori* truths.

A statement was seen as synthetic, on the other hand, if it is not analytic, and synthetic truths were

Verificationism

M Beaney, University of York, York, UK

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Verificationism is the view that the meaning of a (synthetic or empirical) statement is given by its method of verification. A sentence, as used on a given occasion to make a (synthetic or empirical) statement, has meaning if and only if its truth or falsity can – in principle – be determined by experience. Verificationism was the central doctrine of logical positivism (also called 'logical empiricism'), a movement that originated in the work of the Vienna circle in the early 1930s and received its classic statement in A. J. Ayer's *Language, truth and logic* (1936). Although subject to devastating criticism in the 1940s and 1950s, the motivation behind verificationism has continued to influence philosophers ever since, most notably, in the work of W. V. O. Quine and Michael Dummett. Indeed, the basic positivist impulse – to reject anything that is not grounded in sensory experience – goes back at least to David Hume, and has been a significant feature of the philosophical landscape throughout the modern era. Hume's famous words at the very end of his *Enquiry concerning human understanding* are often taken as the definitive statement of the underlying positivist view:

> If we take in our hand any volume; of divinity or school metaphysics, for instance; let us ask, *Does it contain any abstract reasoning concerning quantity or number?* No. *Does it contain any experimental reasoning concerning matter of fact and existence?* No. Commit it then to the flames: for it can contain nothing but sophistry and illusion.

The repudiation of metaphysics was characteristic of logical positivism, too, and this was rooted in the doctrine of verificationism.

The Analytic/Synthetic Distinction

Central to logical positivism was the distinction between analytic and synthetic statements – corresponding to Hume's distinction (implicit in the passage just quoted) between relations of ideas and matters of fact. According to the logical positivists, a statement is analytic if and only if its truth or falsity is determined solely by the meaning of its constituent terms. 'All bachelors are unmarried men,' for example, was seen as true in virtue of the meaning of the term 'bachelor.' Analytic truths were regarded as both necessary and *a priori*. Their necessity was seen to lie in their tautological nature, a view that the logical positivists took from Ludwig Wittgenstein. Since, on their account, analytic truths could be judged to be true merely by knowing their meaning – without needing to consult the world in any way – they were also regarded as *a priori* truths.

A statement was seen as synthetic, on the other hand, if it is not analytic, and synthetic truths were

regarded as both contingent and *a posteriori*. It was in explaining synthetic statements that the doctrine of verificationism was formulated. According to this doctrine, the meaning of such a statement lies in its method of verification. A statement is meaningful if and only if its truth or falsity can in principle be determined by experience, that is, be derived in some specified way from the truth of one or more observation statements – statements that record the direct result of an observation. This characterization immediately raises two questions. What exactly is the relationship between the statement whose truth-value is to be determined and the observation statements? And what exactly is an observation statement?

Observation Statements

Let us take the latter question first. There was much debate among the members of the Vienna circle in the 1920s and 1930s about the foundations of empirical knowledge and the correct form that observation statements – or 'protocol sentences,' as they were called – should take. In his *Aufbau* of 1928, influenced by Bertrand Russell's appeal to sense data in *Our knowledge of the external world* (1914), Rudolf Carnap sketched a 'reconstruction' of our empirical knowledge on a phenomenalistic base. But he also offered the possibility of a physicalistic reduction, reflecting his rejection of the idea that there is any privileged ontology. (Cf. Beaney, 2004: § 4.) Despite this, however, a physicalist language soon became seen as the preferred form in which the protocol sentences were to be expressed, although debate raged about the relations between the physical and the psychological, and indeed, about the very idea of a 'foundation.' (See, e.g., Carnap, 1932/1933; Neurath, 1932/1933; Schlick, 1934; Ayer, 1936/1937. For an excellent account of the debate, see Uebel, 1992.)

In A. J. Ayer's work, however, influenced by Russell and the British empiricists, observation statements were construed as statements about sense data, and material objects – and indeed, other minds – were seen as logical constructions out of them. The project of logical construction was all the rage among analytic philosophers in the early 1930s (see especially Wisdom, 1931–1933), but it gradually became clear just what difficulties it faced. (For a critique, see, e.g., Urmson, 1962, ch. 10, and more recently, Soames, 2003, I, ch. 7.) More fundamentally, the whole appeal to sense data proved problematic, as the very idea of sense data came under increasing fire in the years that followed. (See especially Austin, 1962, and the essays in section II of Swartz, 1965.)

Strong Verification

Problems arose, then, about the nature of observation statements. But even if we leave these aside, and assume that there is a legitimate class of observation statements, such as expressed by sentences of the form 'The *A* in front of me is a *B*,' there remains the question of specifying the relationship between the synthetic statement whose truth-value is to be determined and the observation statements. The relationship was seen as one of verification. But what is it to verify a statement? A distinction came to be drawn between 'strong' and 'weak' verification. In the strong sense, a statement is verifiable if and only if, as Ayer put it, "its truth could be conclusively established in experience" (1946: 12). More precisely, the notion might be defined as follows: a statement *S* is strongly verifiable if and only if there is some set of observation statements which logically entail *S*. The obvious problem with this, however, is that universal generalizations cannot be strongly verified, since no (finite) set of observation statements, 'A_1 is *B*,' 'A_2 is *B*,' ... 'A_n is *B*', *entails* 'All *A*s are *B*.' Even if all the *A*s that we have so far experienced have been *B*, there remains the possibility that the next *A* we experience will not be a *B*. Yet many universal generalizations are clearly meaningful, so we cannot accept strong verifiability as the criterion for meaningfulness.

Strong Verification and Strong Falsification

This might suggest that we should talk not of verifiability but of falsifiability (as Karl Popper was to urge). A statement *S* is strongly falsifiable, we might then say, if and only if there is some set of observation statements which logically entail not-*S*. Saying that a statement is meaningful if and only if it is strongly falsifiable legitimizes universal generalizations, since it only takes one observation statement as a counterexample to falsify a universal generalization. However, we are then faced with the corresponding problem of existential statements, such as 'There is at least one *A* that is not a *B*' (the contradictory of 'All *A*s are *B*'). Finding an *A* that is not a *B* may verify this statement, but no observation statement could falsify it. Finding an *A* that *is* a *B* neither verifies nor falsifies it. To falsify it we need to be sure that *all A*s are *B*, but as we have just seen, this is not entailed by any set of observation statements that we may have made up to now.

The obvious response to both these problems is to say that a statement is meaningful if and only if it is *either* strongly verifiable *or* strongly falsifiable. But this, too, faces problems. First, there are statements involving more complex or different kinds of quantification,

such as those expressed by sentences of the form 'For every *A*, there is a *B* to which it is *R*-related' and 'Most *A*s are *B*.' Although many of these statements are meaningful, they, too, are neither strongly verifiable nor strongly falsifiable. Second, there are all sorts of statements that scientists make, positing the existence of unobservable things such as electrons, charge, and gravity, whose truth-value cannot be simply deduced from any set of observation statements. Rather, their justification lies in the explanation that they offer of observable events. Talk of strong verification and falsification does not do justice to a fundamental method of science – inference to the best explanation (cf. Soames, 2003, I: 280–282).

Weak Verification

The only answer is to retreat to a weaker notion of verification. In the weak sense, a statement is verifiable (and hence meaningful) if and only if, as Ayer put it, "it is possible for experience to render it probable" (1946: 12). Instead of seeing the important relation as deducibility *from* observation statements *to* the statement to be verified, the focus now is on deducibility *from* the statement to be verified *to* observation statements (which, if true, lend it empirical support). Ayer's initial attempt at a definition may be formulated as follows: a synthetic statement *S* is weakly verifiable (and hence meaningful) if and only if *S*, either by itself or in conjunction with certain other premises, logically entails some observation statement *O* that is not entailed by those other premises alone. (Cf. Ayer, 1946: 15; Soames, 2003, I: 283.) On this definition universal generalizations, existential statements, more complex quantified statements, as well as hypothesized scientific explanations of observable events, all come out as meaningful, since observation statements can be deduced from them.

However, as it stands, this definition has the result that *all* statements come out as meaningful. For consider taking the single additional premise, 'If *S* then *O*.' From '*S*' and 'If *S* then *O*,' '*O*' clearly follows, without following from 'If *S* then *O*' alone. So the notion of verification formulated here is far too weak: the definition is satisfied by any statement whatever. In response, Ayer distinguished between direct and indirect verifiability, restricted what 'other premises' are allowed, and formulated a more complex definition. (Cf. Ayer, 1946: 15–18.) But this too has been found to generate similar problems, with suitable choice of additional premises; and alternative formulations have also been found to be open to objections. (Cf. Church, 1949; Hempel, 1950; Soames, 2003, I: 284–291. But for a recent attempt at reformulation, see Wright, 1993, ch. 10.)

The Influence of Verificationism

If an adequate notion of verification cannot be formulated, then it undermines its role in a critique of metaphysics. One of its purposes had been to distinguish legitimate scientific statements from meaningless metaphysical statements – exemplified for the logical positivists in Heidegger's famous remark that 'Nothingness itself nothings' (*Das Nichts selbst nichtet*) (cf. Carnap, 1932: § 5; Friedman, 2000: ch. 2). But it might well be argued that claims about the doctrine of verification itself are metaphysical statements whose status would be threatened if the doctrine were actually correct. Nevertheless, precise formulations aside, the general idea of verification has had enormous influence on subsequent philosophers. According to some, such as Carl Hempel and Quine, what was wrong was the focus on *individual* statements. Instead, they suggested, influenced by Pierre Duhem (1906), it is whole systems of statements that scientists seek to verify in their empirical activities. What has come to be called the Duhem-Quine thesis, that a scientific hypothesis cannot be tested in isolation, indicates the shift that there has since been from atomistic to holistic conceptions of verification. In the case of Quine, this was famously accompanied by rejection of the analytic/synthetic distinction that lay at the basis of logical positivism (Quine, 1951). But this rejection was only intended to purge empiricism of untenable doctrines, not to repudiate empiricism altogether. For Quine, philosophy and science are continuous, and even analytic statements are subject to revision in the light of empirical research.

Other philosophers who were also broadly sympathetic to verificationism took different approaches. In Dummett's work, for example, in which holism is rejected (cf. 1991: ch. 10), the concern has been to develop a systematically articulated theory of meaning based on the notion of assertion-conditions rather than on the classical notion of truth-conditions. A verificationist rather than traditional conception of truth lies at the heart of Dummett's project, and he has seen in mathematical intuitionism the model for a semantics based on verificationist truth. Dummett has been led to reformulate many traditional debates, such as those concerning our knowledge of the past and future, in terms of the opposition between realism and antirealism, a reformulation clearly influenced by the verificationism of the logical positivists. (See, for example, Dummett, 1993, which starts by paying homage to Ayer. Cf. also Wright, 1993: chs. 9–10.) Despite the flaws in its original articulation, then, verificationism remains an active – though controversial – force in contemporary philosophy.

The term 'vernacular' has numerous and varied uses, both within the field of sociolinguistics and in linguistics in general. Such varied usage has led to misunderstandings among scholars regarding what specifically is being referred to, and the possibility that the varieties referred to as 'vernacular' will be undervalued by both the speakers of the dominant language and speakers of these language varieties themselves.

Within the field of sociolinguistics, there are at least two distinct uses of this term. The first sense of this term in sociolinguistics is exemplified by Poplack (1993), which defines vernacular as "the relatively

homogenous, spontaneous speech reserved for intimate or casual situations … taken to reflect the most systematic form of the language acquired by the speaker, prior to any subsequent efforts at (hyper-) correction or style shifting" (Poplack, 1993: 252). Labov (1972) described this variety as one in which the speaker pays least attention to his or her speech and is the least self-conscious of the varieties in his or her repertoire. For scholars who use the term in this manner, the 'vernacular' is the variety that is acquired first, reveals the "most advanced forms of change in progress" (Labov, 2001), and provides the clearest depiction of whether a linguistic feature is "variable or categorical" (Labov, 2001). According to Labov's Vernacular Principle (Labov, 1972), the vernacular is also the variety that is most systematic, not only with regard to its structure but also with regard to its historical development. This use of the term 'vernacular' therefore equates vernacular varieties with casual varieties.

Wolfram and Schilling-Estes (1998) illustrates a different usage, by defining vernacular varieties as "varieties of languages that are not classified as standard dialects" and comparing this usage to the use of 'vernacular' to mean "local or native" (Wolfram and Schilling-Estes, 1998: 13). They contrast standard varieties, which they suggest are defined by the lack of nonstandard features in the variety's grammar, to vernacular varieties, whose grammars contain such nonstandard features. However, they point out that vernacularity "exists on a continuum so that particular speakers may exhibit speech which is more or less vernacular." This usage therefore equates vernacular varieties with nonstandard varieties.

The two varying usages of this term are further illustrated by the use of the phrase "vernacular culture index," as used by Cheshire (1982) and Edwards (1992). For Cheshire, the index was calculated by subjects' participation in activities such as carrying weapons, choosing clothing styles, and fighting, while for Edwards, the index was calculated by subjects' ties to local neighborhoods via the location of their families and their jobs, and their desire to remain living in the area. Thus, for Cheshire, the vernacular culture is defined as nonstandard or counter culture, while for Edwards, it is defined as localness.

Meyerhoff and Niedzielski (2003) placed global variants in opposition to local variants, and they suggested a mechanism by which global variants can become local, in just such cases as they become part of a speaker's vernacular. Although they use 'vernacular' as analogous to systematic and least self-conscious varieties, as described above, they show how both of these senses can be incorporated into the concept of 'vernacular.'

In the realm of general linguistics, particularly field linguistics, 'vernacular' is used to refer to local languages, as opposed to a lingua franca, official standard, or a global language. For example, the Ethnologue website refers to the local languages spoken in Papua New Guinea and the aboriginal languages of Australia as the "vernacular languages," which, on this site, are contrasted with English. The Summer Institute of Linguistics website refers to local languages as "vernaculars," for instance, in discussions of literacy in languages other than English. Comparable usage of this term is seen on the phrase "vernacular literacy," which means literacy in a language other than a standard or global language, and often includes literacy in nonstandard dialects of a global language.

The juxtaposition of 'vernacular' and nonstandard dialects, however, raises the inherent danger that the negative stereotypes associated with nonstandardness will become associated with the vernacular varieties. This is one reason some scholars prefer to use 'African-American English' instead of 'African-American Vernacular English.'

A Bird's Eye View of the Middle Ages

On the level of facts, the earliest studies in vernaculars consist, for example, of the first grammars of the various national languages, where otherwise only grammars of Latin were to be found, and of the first dictionaries in which lexemes were culled not primarily for learning Latin. In addition, there is teaching material that aimed at the support of the learning of spoken languages. These facts are not too exciting in themselves, certainly not if seen from a much later point of view such as that of our 21st century. They are, however, noteworthy in their indicative value. They show that new ideas had entered the attitudes towards vernaculars at the time of publication – ideas that were opposed to the previously unchallenged position of Latin. The year 1450 can serve as a historical threshold for the beginning of this development. In order to see the earliest studies of the vernaculars in their proper ideational perspective, the position of the Latin language in the earlier era must be sketched out.

Linguistically speaking, the Middle Ages in Europe were a real *res mixta*. The language of the intellectuals, exclusively represented by the clergy of the Roman Church, was Latin. This exclusivity meant the leading members of society spoke and wrote a language that was different from that of the plain people and was largely unintelligible to them. As the language of the military rulers, it had been brought to the continent north of the Apennine peninsula, first of all in a variant spoken by the soldiers of the Empire, i.e., by badly educated speakers. Subsequent to the variant of the soldiers, the variant of the Roman intellectuals – the historians, philosophers, orators, and men of letters – became known. In addition to the new religion, it was their culture and their language that gave the newly emerging kingdoms and even the new Church cultural substance. Latin infiltrated the various vernaculars to which it was juxtaposed. In the countries today called 'Romance,' new languages came into being; in the countries called 'Germanic' and 'Slavonic,' the indigenous languages prevailed with obvious changes, most of all in lexis.

When the military personnel and the whole Empire disappeared, their language stayed on – the vulgar idiom of the soldiers probably less so than the refined idiom of the learned that had been conveyed to script. The result was a general bilingualism of the newly developing society under the guidance of the Roman Church.

The Latin of the Middle Ages, as documented between (roughly) 800 and 1500, can, in modern terms, be defined (i) as a second language, (ii) as a group language, and (iii) as a register for special purposes. As a second language, it had no native speakers. It was not acquired naturally as first languages are, but had to be taught. As a group language, it marked its speakers as being the members of an educated class (and the others as not belonging to it), and as a register for special purposes, it was shaped and reshaped according to the special communicative needs it had to serve, most of all, in religious and academic contexts. In this process, it became alienated from its classical origins. As a consequence of all this, the teaching of any theoretical knowledge went, for a long time, together with the teaching of the language. Latin was the medium but also the matter. Reflecting on Latin was therefore, in many cases, combined with reflecting on teachability and learnability. The Latin textbook already appeared as a new genre in the works of the insular grammarians (i.e., in the 6th to the 8th centuries), and the Latin word list emerged in the 8th century from the glosses of readers and scribes who struggled with the foreign texts.

Admittedly, this medium was not altogether new. Donatus Aelius (4th cent. A.D.) and Priscian (6th cent. A.D.), the two leading Roman grammarians whose works dominated the whole of the Middle Ages (and even the ensuing centuries of Humanism), had already thought of their own works as being didactic grammars. It was their endeavour to teach classical Latin at the expense of the vulgar version. This aim is why they stressed the formal characteristics of the language more than anything else. We know from the *Institutio oratoria* of Marcus Fabius Quintilian (fl. 35–96 A.D.) how this instruction was accomplished in Roman schools. Because of the Roman predilection for Greek culture and the Greek language, there was also much foreign grammar teaching done in the Roman Empire.

Glossaries and onomastica were compiled in Rome from the 3rd century B.C. onwards in order to comment on the language of individual authors. All of the grammarians as well as the glossators had their Greek predecessors. Hence, reflecting on language in the two most essential areas, grammar and lexis, always had a didactic dimension. But the medieval authors had to do so under new constraints, *viz.* the keeping alive of a foreign (second) language *vis-à-vis* several indigenous ones that ruled everyday life. For the vernaculars, their strongest asset in this contest certainly was natural acquisition. In the many post-Roman countries, generation after generation acquired their

mother tongues with natural ease and used it accordingly. Although many of these native speakers went to schools afterwards in order to learn Latin and its culture, they remained at the same time native speakers of their vernaculars. They were citizens of two linguistic realms. The strength of the indigenous linguistic undercurrent must have been present in the individuals' everyday life, of which we regrettably know hardly anything. It certainly emerges in the works of heroic and courtly literature.

Obviously, there never was a chance (or danger) of Latin becoming a vernacular after the Romance languages had consolidated (i.e., after 1000). We can imagine that outside of intellectual discourse, much phatic communion and small talk occurred in Latin in the monasteries. Moreover, the linguistic system, in particular lexis, deviated more and more from its classical norms. Note, for example, the philosophical terminology developing over the centuries of scholasticism. This development was not a sign of deterioration (as the Humanists later maintained) but of an independent development according to present needs. Nevertheless, Latin retained in the status of a foreign idiom, to be taught in formal settings (schools) and to be used by the knowledgeable in specific domains (theology, philosophy). It nowhere ousted a vernacular. As far as the influence of the Roman Church reached, this presence resulted in a unified, theology-ridden European culture expressed in one idiom, below which, however, several national idioms were alive and creatively used. They were not the object of scientific study. By common assent, 'language' meant Latin and 'grammar' meant Latin grammar.

The general appreciation of Latin as a prototypical language was not only warranted by historical development and the sheer weight of facts that resulted from it. It also had a theological background. Latin was the language of the Bible, though not the original one. During the Middle Ages, it was the language of Revelation, inherited from the Greek and Hebrew versions of the canonical texts. It was also the language of the church since the works of the Church Fathers had been translated into it. There was, therefore, no problem in equating the structures of this language with the structures of thinking, as the *Modistae* did in the 12th century.

When, around the middle of the 15th century, the first studies of the vernaculars appeared, it meant challenging a cultural pattern that had been dominant for eight centuries, with a tradition of even more centuries behind it. The languages that expressed various national cultures below the common European one rose to the level of general interest and, if not already gaining a position of superiority over Latin (as from the end of the 18th century and the cult of nationalism in linguistics), at least stood on a par with what had so far been acknowledged as Europe's sole linguistic tongue. This elevation of the national languages meant challenging many more assumptions than just linguistic ones. Against the background of medieval Europe, the development rightly appears as revolutionary. The question is what caused and stimulated this process.

Of course, answering this question would mean explaining everything that is covered by the terms 'Renaissance,' 'Humanism,' and 'Reformation,' i.e., the intellectual and mental, the religious, philosophical, political, and societal processes that separate the modern world from the medieval one. Though occurring simultaneously, these processes were individual ones in each country. Note, for example, the different events constituting the Reformation in England, Germany, Bohemia, France, Spain, and Italy. With respect to the early studies in vernaculars at the cost of the unique acknowledgment of Latin, these divergences, however, had the same result. Between 1443 and 1583, the first grammars appeared in these languages. Different settings and different events must, therefore, have had so much in common that they produced homogeneous effects, for example:

1. the increasing wish for independence of the national churches from Rome and the establishment of new denominations, boosted not least by the translations of the Bible from Latin (Greek and Hebrew) into a vernacular and under the pretext that such translations strengthened the direct relation between the individual human being and God
2. the increasing consolidation of nations as centralized political entities unified not only by titles of possession held by feudal families and their marital relations, but also by a common national language
3. the increasing use of books made possible by the printing press and other innovations like the manufacture of paper and lenses for reading, recruiting a growing number of readers and establishing a new intellectual culture, independent of the usual centers of learning in monasteries, and the establishment of universities
4. the increasing use of long-distance trading routes not only along the coasts (by ship) but across the continent, crossing language barriers and with trading posts set up in towns, causing long-term stays of people in foreign language areas.

In one way or another, the first studies of the vernaculars were a part of one or several of these development(s) by indicating either religious or political or intellectual or economic innovations or a

combination of these. Classical Latin regained its position as a historical language and represented a much admired past. It continued to be taught for this reason. Medieval ('new') Latin sank into oblivion and derision. Latin and the living languages had now in common that they were constructed 'according to rules.' They could be subjected to the same kind of analysis.

The contest between Latin and the European vernaculars appeared in various genres of text, among them grammars, dictionaries, textbooks, letter guides, abecedaries, treatises on rhetoric and style, books with an arrangement of languages in parallel, deliberations on language origin and history, notably the biblical story of the Tower of Babel, translations (above all of the Bible) and comments on translating, etc. Only the first two will subsequently be discussed in any detail. The aim is to find out what the individual works of the two genres have in common and what is different. Theological arguments in the context of Bible translations will not be considered, because they must be seen in their own complex conditions and are the best known in this historiographical field.

Dante's Revolutionary Work

Long before the wave of vernacular grammars set in, Dante Alighieri wrote his two treatises *Il Convivio* (1304–1305) and *De vulgari eloquentia* (shortly after 1305), which may be considered as "the vanguard of the movement leading to the 'discovery of mother tongues' in Western countries" (Gensini, 1996: 220–221). Without paying attention to slight divergences between the two texts, we evaluate them as the earliest powerful statement of the superiority of vernaculars over Latin. The reasons given would today be named psychological and sociological. According to Dante, the vernacular is inherited from one's parents, learnt by imitation of one's mother, fundamental for communication and learning – even for learning Latin – and closer to the heart of people. In use, it is much more convenient than Latin, but just as expressive. Unlike Latin, it is more easily understood and read by a greater number of people. It is called the *locutio prima* against the *locutio secunda* of formal grammar. Dante admitted that vernaculars are less stable than Latin and are corruptible over the course of time and by spatial dispersion. But he regarded these changes as natural. In comparison, the stability of Latin is artificial. Although Dante agreed with the historical theory of his time by attributing linguistic variety and change to the sin of Babel, he acknowledged them as being natural and not amendable by the formalized grammar of a universal idiom. The three language groups (Germanic, Greek, and Latin) that he distinguished and the 14 dialects that he finds in Italy are therefore on a par with the artificial product of Latin. Dante even gave his linguistic arguments a national emphasis by criticizing these dialects as being corrupted and not fit to be a national idiom, eventually defining the 'illustrious dialect' that he is looking for and that he, of course, hopes to create himself.

It is obviously not accidental that for this first controversy about a vernacular, the Italian dialects and Latin were taken as its objects, because the close relationship between the two allowed minute comparisons and made the author become aware of such linguistic qualities as naturalness and formalization, stability and change, information and expression, etc.

Dante's deliberations almost beg for comparisons with recent concepts like *langue/parole*, system/use (performance), communicative competence/grammatical competence, communication/sign, native language/foreign language, etc. There has also been an attempt to trace the influence of the *Modistae* in Dante with a maintained parallelism between the structures of (any) language and of thinking. In particular, the idea that the first language is expedient for the learning of others is reminiscent of similar ideas, for example, of Ludwig Wittgenstein. It almost goes without saying that the revolutionary impetus of Dante's ideas was not recognized during his lifetime and for quite a while after that. He must have foreseen this delayed recognition. So he published his attack against Latin – in Latin. This seemingly absurd fact will often be found in the following centuries. "D[ante]'s ideas made themselves felt indirectly, however, through the extraordinary impulse his poetry gave to the development and use of vernacular and to the 'naturalistic' view of language he conveyed through it" (Gensini, 1996: 224).

First Vernacular Grammars

The following short reports will show that between 1437 (Alberti) and 1586 (Bullokar), the first grammars of Italian, Spanish, French, German, and English were written, testifying to the common wish of bringing the vernaculars into their own. Publishing such grammars meant establishing the languages as entities in their own right. The ways in which each language was established, however, were different in each case.

The architect and *uomo universale* Leon Battista Alberti is generally credited with having written the first Italian (Tuscan) grammar, although his so-called *Grammatichetta vaticana* (between 1437 and 1441) was not published in print until 1908. It is therefore

difficult to assess its influence. There must, however, have been copies around in the 16th century, for example, in the library of Lorenzo the Magnificent. It is a practically oriented small book, based on contemporary Tuscan, using word classes according to Priscian, and aiming to show that dialects, like the ones spoken at Alberti's time, had structures just like Latin had, which was itself the outcome of various dialects. In this earliest example, it already becomes obvious that most grammarians saw no choice but to map their living language onto the 'dead' one, Latin, if they attempted to show that Latin was not unique. They were bound to it, even in curbing its influence.

Alberti was ahead of his fellow grammarians Giovanni Francesco Fortunio (*Regole grammaticali della vulgar lingua*, 1516) and Pietro Bembo (*Prose della volgar lingua*, 1525), who are the first two relevant Italian authors. They have in common the quest for the ultimate norm of a dialect that would then qualify for being the national Italian language; they differ in that Fortunio found it in modern written Tuscan as exemplified by the great canonical authors Dante, Petrarch, and Boccaccio, whereas Bembo found it in archaic Tuscan. Both use the Latin word classes, though Bembo does so by avoiding the technical terminology of traditional grammarians. Fortunio wrote a pedagogical grammar with numbered rules, Bembo wrote a dialogue with no rules for memorization at all but with the discussion of historical issues that were to support his rigorous classicism. Fortunio also had an interest in harmonizing orthography for the benefit of the growing printing industry.

For other Italian grammarians of the 16th century, see Marazzini (2000).

The first grammar of a modern European language written according to a strict method is Antonio de Nebrija's *Gramática Castellana* (1492). The political conditions of the work are well known. The consolidation of the state under Ferdinand and Isabella and the dawn of the Golden Age of the empire demanded the parallel consolidation of a national language. The structure of the book is extraordinary. Books 1–4 described Spanish for native speakers with the aim in mind that the knowledge of their language should help them learn Latin. Its order (*orden natural*) employed the usual Latin categories, but added general linguistic knowledge and gave examples of structures from several languages (Latin, Greek, Hebrew, French, Andalusian, etc.). Book 5 described Spanish for nonnative speakers in a different order (*orden de la doctrina o artificial*), which is a phonetical and morphological overview. A 'book' for native speakers to learn their own language (better) was, however, missing. The innovative element of this grammar was obviously the idea that it provides knowledge of the native Spanish (Castilian) language, because this knowledge is the stepping stone for learning any foreign language, in this case Latin. The teaching of Latin itself was conceived in quite traditional terms. Nebrija himself also wrote a Latin grammar, which was even more successful than the Spanish one.

For this idea, Nebrija had forerunners in the so-called *grammatica proverbiandi*. They were to be found in Italy (where he lived for many years) and in Spain. They used expressions from the respective vernaculars in order to explain Latin structures. In modern terms, they can be called contrastive grammars (or, at least, grammars with contrastive elements). The rich supply of Spanish, Catalan, Andalusian, and Valencian examples makes them a first-rate source of medieval foreign language teaching in the region. Latin and vernacular examples were systematically translated into both directions. Retroversions uncovered many instances where the structures of the language pair did not coincide. Castilian, for example, sometimes uses prepositions where Latin uses synthetic cases. The explanations of such incongruities in the Latin version are called *supletio*. The treatment of linguistic contrasts in these grammars has been called the nucleus of Spanish grammatography.

For other Spanish grammarians before and after Nebrija, see Esparza Torres (2000) and Niederehe (2002).

The grammatography of French has a very special feature: its early works were written not in the country and not for natives, but in England and for speakers there who wished to learn the foreign language. The outstanding work, indeed the first comprehensive and methodical grammar of the French language in general, was *Lesclarcissement de la langue francoyse* (1530) by John Palsgrave – a book written in English in spite of its French title. But there were even earlier treatments of the matter that Palsgrave obviously knew, namely those by Alexander Barclay (*Here begynneth the introductory to wryte and to pronounce frenche*, 1521), Pierre Valence (*Introductions in frensshe*, 1528), and Giles du Wes (*An introducterie for to lerne to rede to prononce and to speke Frenche trewly*, 1532–1533). Together with the even earlier *Dialogues in French and English* (1483) by William Caxton, these books testify to the general interest of English speakers (often of noble descent) in learning French. The books are not grammars in the narrow sense, but textbooks. Palsgrave's book eclipsed them all in massiveness, comprehensiveness, and rigor. It is not just a grammar, either. It also contains extensive lists of French lexemes with their English equivalents. So, it testifies simultaneously to the general challenge to Latin, to the methods of

foreign language teaching, and to vernacular lexicography. Widely read as Palsgrave was, he took his observations of the language and examples from 'good' French literary works. As the great model for his book, he mentioned the Greek grammar by Theodorus Gaza (1495).

The structural basis of Palsgrave's grammar of French was the common framework of Latin grammars according to Donatus. To this extent, he was not different from all the other vernacular grammars. However, he found nine word classes in spite of eight, because he adds the definite and indefinite article. In the three 'books' of his work, he carefully distinguished between rudimentary and advanced grammar teaching, thus giving his book a clear overall progression. Moreover, he carefully noted "[T]he differences of Phrasys betvene our tong and the French tong." Again, language contrast was made the means of foreign language teaching and learning.

"Au début du XVIe siècle, il n'existe encore aucune grammaire française en France" (Kristol, 2000: 766). However, it soon came into being. Geoffroy de Tory (*Champ fleury auquel est contenu lart et science de la deue et vray proportion des letters*, 1529), whom Palsgrave knew, initiated the same idea that 'rules' like those found by Donatus, Priscian, and Quintilian could be applied to French just as to Latin. Jacobus Sylvius (Jacques Dubois, *In linguam Gallicam isag/o/ge una cum eiusdem Grammatica Latinogallica*, 1531) wrote the first French grammar to appear on the continent in Latin, probably because he thought this language to be a means of common understanding at the University of Paris and thus a platform for learning French. His grammar was entirely modeled on Donatus and Priscian. He elaborated on phonetics, etymology, and grammatical morphology, and declared the dialect of Picardy to be the ideal form of French. Johannes Drosaeus (Jean Drosée, *Grammaticae quadrilinguis partitiones*, 1544) used the same traditional approach by showing that Latin structures could be used in the same way for analysing Hebrew, Greek, Latin, and French. Latin was therefore regarded as 'universal.' Only with Louis Meigret (*Tretté de la grammare françoeze*, 1550) did French grammatography come into its own. He was interested in spoken language and maintained that a living language could be described systematically just as a 'dead' one. For him, this fact does not rest on the stability of a morphological system but on its functioning. "[L]es Français se parlent et se comprennent." This function is what French has in common with Greek and Latin. "Sur cette base conceptionelle, Meigret développe une description synchronique du français dans le meilleur sens du terme" (Kristol, 2000: 767).

For other French grammarians, see Kristol (2000) and Colombat (1998: 111–149).

In Germany, grammatography emerged from pedagogical writings like abcedaries and readers which, besides teaching people, work tentatively towards a homogenizing of the many regional dialects. It was Valentin Ickelsamer who wrote the first book with the word *Grammatik* in its title (*Ein Teütsche Grammatica*, 1534). It is not a proper grammar in the usual (i.e., Latin) sense, although the eight word classes of Donatus appear as if taken for granted. It is an appeal to grammarians, teachers, and everybody to be aware of the value and dignity of the German language in order to be able to read and to write and to learn other languages – above all Latin. Thus, it is a general pedagogical treatise showing the expressive possibilities of special syntactical patterns (like participles), the origin of word meanings, the controlled use and cultivation of language.

The first grammars proper were written in Latin, although two of them had German titles, and faithfully followed Philipp Melanchthons's highly influential *Grammatica Latina* (1544) which was modeled on Donatus. Laurentius Albertus (Ostrofrancus, *Teutsch Grammatick oder Sprachkunst*, 1573) struck a national note. The age, richness, and beauty of German, he wrote, merits German being treated according to the accepted rules of grammar. He maintained that all languages have the same grammar and that, as a consequence of this, grammatical knowledge in one's own language facilitates learning foreign ones. With a similar argument, Albertus Ölingerus (*Underricht der Hoch Teutschen Sprach*, 1573) intended his grammar to help French speakers learn German. Johannes Clajus (*Grammatica Germanicae Linguae*, 1578) followed Albertus and Ölingerus in explaining German using Latin categories. A side-by-side reading of the three books shows the differences that can arise when the model (Latin) and its adaptation (German) do not agree, for example, where the ablative is concerned.

For more German grammars, see Moulin-Fankhänel (1994) and Rössing-Hager (2000). The first German grammar written entirely in German is that written by Johannes Kromayer (*Deutsche Grammatica. Zum newen Methodo der Jugend zum besten zugerichtet*, 1618). It was meant as a preparation for the teaching of Latin.

In the case of English grammatography, the national background is particularly strong, as it coincided with the Elizabethan era. Richard Mulcaster (*The first part of the elementary*, 1582) set the tone with the much quoted "I loue Rome, but London better, I fauor Italie, but England more, I honor the Latin, but I worship the English." His book, though

not a proper grammar, is a general plea for mother tongue education in England, in particular concerning spelling. William Bullokar (*Pamphlet for Grammar*, 1586, usually called *Bref Grammar*) was the first to write a proper grammar of the national language, in which he truly followed the leading authors of Latin grammars in England at that time, Thomas Linacre, John Colet, and William Lily. It was the only way of proving that English was a language governed by 'rules,' just like Latin. Lily's (and Colet's) *Shorte introduction of* [Latin] *grammar* (1547), which had a complicated history before appearing, was seminal for Bullokar, because it gave Latin as well as English examples matching the Latin paradigms. Paul Greaves does very much the same in his *Grammatica Anglicana* (1594), although he explained his grammar as *praecipue quatenus a Latina differt ad unicam P. Rami methodum concinnata*. There is more intention than realization in this. The later works of Alexander Gill (*Logonomia Anglicana*, 1619) and Alexander Hume (*Of the Orthographie and Congruitie of the Britan Tongue*, 1617) are much more progressive in this respect. They use the so-called sign theory (Vorlat, 1975). According to this, certain structures of Latin – i.e., *casus*, *modi*, and *tempora* – are replaced by different 'signs' in English – i.e., by prepositions, auxiliaries, or interjections. This attempt is the first systematic one at differentiating and simultaneously parallelizing Latin and English in their structures. Grammatographers like Charles Butler (*The English Grammar*, 1633) and Ben Jonson (*The English Grammar* [...], 1640) followed this model. The most original author in this respect was John Wallis in his grammar of English, written in Latin (*Grammatica Linguae Anglicanae*, 1653), in which he replaced the usual explanations by word classes and declensions by so-called aggregates, i.e., syntactic word groups below the sentential unit, which prefigure the much later concept of phrases and constituents. It was a long time before this ingenious idea was generally accepted. Many other grammarians adopted the traditional word class system with only little alterations (Michael, 1970).

For more English grammarians, see Colombat (1998) and Hüllen (2005b).

Similar observations and statements can be made about all the European languages. For the development of Slavic languages, see Tavoni (1998).

First Vernacular Dictionaries and Textbooks

As is to be expected, the emergence of vernacular dictionaries occurred together with that of grammars – sometimes even initiated by the same author. The general motives and reasons for historical processes in grammatography and lexicography are the same, although the technical features of dictionaries entail at least one important difference: grammarians effected the change from Latin to the vernaculars mainly by perpetuating the old grammatical system, i.e., by modeling the new grammars on the old ones. (This preservation actually happened up to the end of the 19th century.) Dictionary writers could preserve only to a much smaller degree. They kept the order of the macrostructure, e.g., the alphabet, and the elements of the microstructures of old dictionaries – the lemma, its function in grammar, the synonym, the definition, the quotation, the encyclopaedic comment, and others, in varying selection – but the way in which these items were kept changed dictionaries so drastically that the continuity was disrupted here much more quickly than in the case of grammars.

The long-term development of lexicography is pan-European. Everywhere, Latin codices were glossed with varying density, either between the lines or in the margins. These glosses were set down in bilingual lists (*glossae collectae*), where they often fell into semantic clusters, because of the special vocabulary of the texts. This development prepared for the specialized vocabularies of later centuries. The lists of glosses were extended and combined, and many were alphabetized, so that they had either a semantic or a formal order. When printing provided the technical possibilities, word lists and glossaries eventually expanded to the size of dictionaries with Latin lemmata and juxtaposed vernacular interpretations. Over the course of time, they became a regular teaching and learning aid.

More than anything else, this development of glosses increased their usability for translation. It proves that translation was indeed the universal method of acculturating to the classical texts and their contents. Everywhere in Europe, Latin was the early medium of knowledge and culture but, again everywhere in Europe, the respective vernaculars were the metalanguages to Latin. Without them, the rich corpus of Latin works would have been empty. Nothing demonstrates the continuous mental relationship between formally trained Latin and the naturally acquired mother tongue better. Glosses and the dictionaries emerging from them therefore had a didactic element. They served the teaching of Latin. With the rising standard of learning, some enormous dictionaries came into being that forewent the learning aspect and served as works of reference for the more modest didactic ones. They are the *Elementarium doctrinae erudimentum* by Papias (middle 11th cent.), Osbert of Gloucester's *Panormia* (12th cent.), *Magnae derivationes* by Hugutio of Pisa (c. 1192), Guilelmus Brito's *Exposiciones*

vocabulorum biblie (between 1248 and 1267), and the *Summa quae vocatur catholicon* by Johannes de Janua (Balbus, finished 1286).

The semanticizing of Latin texts was done by simple reading and by translation. In the bilingual dictionary, this format necessitated the sequence 'Latin lemma (unknown) followed by explanatory vernacular expression (known).' Where this order was reversed into 'Vernacular lemma (known) followed by complementing Latin (unknown),' the dictionary obviously no longer served the reading and translating of Latin but rather the speaking and writing. Teaching changed from the receptive to the productive skills and was probably more advanced. Nevertheless, handling Latin was still its sole aim. The new arrangement, which was often a simple reversing of an established order, may signal a growing awareness of the importance of the first language for the learning of any further one. But it was still the Latin language that was envisaged as the learning target. Nevertheless, the dictionaries that juxtaposed Latin and a vernacular had the important second effect of stabilizing the lexis of spoken vernaculars – the store of their words, phrases, and idioms, and, above all, spelling. Many first sources are to be found in them that prove the occurrence of words, the introduction of new or the loss of old ones in language use. What was written down in order to support the learning of Latin also testified to the development of the vernacular at a time when the vernacular was not thought to be worth documenting.

Vernaculars came fully to the fore only when monolingual dictionaries in Italian, Spanish, French, German, and English (and the other European languages) began to appear and when the same happened with multilingual vernacular dictionaries in various combinations. Only then was the conceptual threshold reached beyond which it was thought possible and worthwhile to collect the lexemes of vernaculars – just like their structures in grammars. There are at least two diverging interests behind this. One is that, stimulated by the concepts of Humanism and the Renaissance, the national organization of the continent made progress. National languages became the various nuclei around which people gathered; it was the bond that tied their community together. We can trace this process by looking at the national lexicography as practiced in the various countries. The other one is that, stimulated by the practice of daily life, national languages gained in communicative importance outside their indigenous countries. They were learnt as foreign languages wherever this study was possible and feasible. Since the middle of the 15th century, teaching and learning spoken languages other than one's own became a necessity for many people. We can trace this process by looking at international (multilingual) lexicography as practiced in many countries of the continent irrespective of regional idioms. They list several languages in parallel and are part of the development of each vernacular concerned. To them belong two great textbook families. The one, *Introito e porta* (1477), written by Adam of Rotweil (dates unknown) after the model of a textbook by Master George of Nuremberg, originated in Venice, exploiting the lively trade relations between this town and some cities in the south of Germany. It was a textbook for Italians to learn German. It consisted of semantically arranged word lists with little grammatical information. It grew into a rich stemma of versions with as many as six languages. The other, *Colloquia et dictionariolum* (before 1530), written by Noel de Berlaimont (dates unknown), originated in Antwerp, exploiting the atmosphere of the highly cultivated Netherlands located between French, Low Dutch dialects, German, and English. It was a textbook for Dutch people to learn French. It consisted of dialogues set in typical scenes of everyday life and 'little' dictionaries matching them. It grew into an equally rich stemma of versions with as many as eight languages. The places where both books were printed were the centers of the new industry on the continent. Many of the multilingual editions also contain Latin lexemes that serve as a kind of common point of reference. Both textbook types were probably meant for self-instruction. Of course, there were also textbooks in existence that did not belong to either of these families, although their design was quite similar. Above all, these ones pertained to the use of dialogues. We find them, for example, in England, where the languages of the continent, notably French, Italian, and Spanish, were taught, but where people used their own teaching material. There were, for example, textbooks for the teaching of Italian written by Claude de Sainliens.

There are also multilingual dictionaries that were not designed as textbooks but as dictionaries proper. Most famous among them is Ambrogio Calepino's (1435?–1509?) Latin and Greek dictionary (Venice, 1502) which gradually grew into an 11-language edition and was known all over Europe. Although a dictionary for explaining Latin in the first place, it eventually mirrored the state of all the influential European languages. Equally famous is the *Nomenclator omnium rerum propria nomina variis linguis explicata indicans* of Hadrianus Junius (Adriaen de Jonghe, 1511–1575; Antwerp, 1567) which was published in nine languages. Its topical arrangement made it the outstanding example of a dictionary that served linguistic as well as encyclopaedic purposes. Independent of these two, there were a number of

dictionaries devoted to the two older languages, Greek and Latin, and one or several new ones. All of them put the languages of the various regions (countries) into the wider European context.

For the importance of textbooks by Johannes Amos Comenius and their editions in various languages, see Hüllen (1999).

The Italian scene showed some surprising details. Concerning bilingual dictionaries, the country seemed indeed to have profited much more from its European reputation as the origin of the Renaissance than from its own initiatives. Italian and French works appeared in France (e.g., Gabriel Pannonius: *Petit vocabulaire en langue françoise et italienne,* Lyon, 1578; Jean Antoine Fenice: *Dictionnaire françois et italien,* Paris, 1584), and in the Netherlands (e.g., Nathanael Duez: *Dittionario italiano e francese/ Dictionnaire italien et François,* Leiden, 1559–1560). Italian and English works appeared in England (e.g., John Florio: *A Worlde of Wordes,* London, 1598, *Queen Anna's New World of Words,* London, 1611). Of the Italian and Spanish works, one appeared in Spain (Christobal de las Casas: *Vocabulario de las dos lenguas toscana y castellana,* Sevilla, 1570), and the other one – finally – in Italy (Lorenzo Franciosini: *Vocabulario italiano e spagnolo/Vocabulario espanol e italiano,* Roma, 1620). All this shows that vernacular dictionaries were produced where cultural and economic interests were active, even without being confined to the country itself. Bilingual lexicography was more a European affair than an Italian one.

The discussion concerning which Italian dialect should be accepted as the national norm led to a number of monolingual dictionaries that presented the language of the three great authors Dante, Petrarch, and Boccaccio as linguistic models, and others that favored the idea of creating a mixed norm taken from the outstanding features of various dialects. A wave of dictionaries came into being with Italian lemmata, definitions, and quotations – i.e., dictionaries of Italian for Italians. Outstanding are, for example, the works of Francesco Alunno (*Le richezze della lingua volgare*, 1543; *La fabrica del mondo*, 1548) and Giacomo Pergamini (*Il memoriale della lingua italiana*, 1602). They (and others) became the basis on which the famous *Vocabulario degli Accademici della Crusca* was constructed and published in 1612. In 1583, the *Academia della Crusca* had been founded with the one intention in mind of creating a book like this one. It gave priority to the dialect of Florence in the *trecento*, and, in doing so, conformed with the ideas of the most eminent grammarian, Pietro Bembo. Of course, there was much criticism, in particular concerning the following editions (1623, 1691, and later). But the outstanding national importance of the Crusca dictionary was never queried. In Europe, notably in Spain and France, the Academy and its dictionary were appreciated as the adequate solution to an urgent national problem.

Elio Antonio de Nebrija, the instigator of genuine Spanish grammar writing, is also the instigator of genuine Spanish lexicography. He published the *Lexicon ex sermone latino in hispaniensem* (1492) and the *Dictionarium ex-hispaniensi in latinum sermonem* (probl. 1495). Although the Latin vocabulary of both books is largely dependent on Johannes Balbus, they are a great lexicographical achievement in their own right. As was his grammar, Nebrija's two dictionaries were meant to serve the teaching and learning of Latin, but became influential documents of the vernacular. They stabilized Spanish orthography, which followed pronunciation fairly strictly, and are excellent documents of the status of Spanish at the time. They proved to be exemplary for other lexicographical works, for example, dealing with Latin and Catalonian, Latin and Arabic, and Spanish and South American (Indian) languages. Although planned for teaching and learning Latin, the author's pride in his national language permeates the whole book.

The first monolingual dictionary that was compiled in order to muster the Spanish language in the Humanist spirit of the *Siglo de Oro*, and no other, is the *Tresoro de la lengua castellana o espanola* by Sebastián de Covarrubias Orozco (1611). Besides the usual lexemes, including idioms and proverbs, and besides many names of persons and places, it contains much factual information that gives the book an encyclopaedic character. Etymologies – according to the standard of knowledge then available – underpinned the antiquity and, in consequence, the excellence of the Spanish language, which was thought to stem directly from Hebrew.

In Spanish (as in other languages), lists of technical terminologies contributed to the development of monolingual lexicography. They started appearing in the 16th century. They were devoted, for example, to nautical terms, to agriculture, botany, and medicine. Written and used by people who lived outside educated circles, they are a frequently overlooked but important, occasionally substandard, way of presenting the riches of one's own language. They often contain craft-specific idioms and phrases.

There was a Catalonian–German edition of *Introito e porta* as early as 1502, published in Perpignan, which testifies to the practical needs of foreign language learning – in this case German – in Spain itself and possibly in the western Mediterranean. It is the

only single-language adaptation of *Introito e porta* to appear (Stegmann, 1991).

Apart from this text, much material appeared on the continent, outside Spain, for teaching Spanish as a foreign language. In Italy, the Spanish-born pope Alexander VI stimulated the knowledge of his home tongue enormously. During the reign of Charles V, when the center of Europe lay in Madrid, the interest in the language grew generally, as a result of the almost omnipresent political and economical power of Spain. It became the most widely learnt foreign language in England and on the continent.

The *Real Academia Espanola* was founded in 1713, its dictionary appeared in 1726 and 1739. It was **the** authoritative presentation of the Spanish vocabulary according to the norms of the time, and has remained effective in this sense ever since. Unlike the dictionary of the Italian academy, however, on which it was modeled, it confirmed and stabilized the status of the national language almost one hundred years after Spain's great lexicographers had already done so.

Lexicography in French progressed along the same lines as in other languages, without, however, lacking individual features. It started with glosses and developed into Latin dictionaries of a high standard. The way from here to the lexicographical treatment of the national vernacular can, in its initial stages, be traced in the works of one man, Robert Estienne. In 1531, he published the monolingual *Latinae linguae thesaurus*, a comprehensive and perfect book that deserves to be compared with the famous Calepino. It was the author's intention to cleanse the Latin language of all medieval remains, to verify the correctness of meaning definitions, and to find classical quotations for each of them. Where he found Latin meaning definitions to be insufficient, he replaced them by vernacular ones – this deviation being a first one from the otherwise strict Latin monolingualism. In 1538, Estienne published a shortened version of the *Thesaurus*, the *Dictionarium latinogallicum*, with many old and rare words deleted, but many more French definitions inserted than in the 1531 book. Only one year later, the *Dictionaire francoislatin*, a turned-over version of the *Dictionarium*, came out. It was called "[le] premier relevé alphabétique de mots français suivis, outré leur equivalent latin, de développement en langue nationale" (Quemada, after Bray, 1990, 1793). The book has the significant subtitle *contenant les motz & manieres de parler Francois, tournez en Latin*. In spite of its Latin starting point, it included the domains of the common French language use that had so far been excluded from dictionaries. This progress towards a vernacular dictionary was continued by Jean Nicot in his *Thresor de la langue francoyse, tant ancienne que moderne* (1606) and finalized by Maurice de La Porte's *Epitheta* (1571), the first monolingual dictionary in the full sense which presents French in its use as a national vernacular.

As the third country in Europe after Italy and Spain, France stabilized its national vernacular in an authorized version through the dictionary of the *Académie française*. This solidification happened as late as 1694, because the noble society, founded in 1635, took so long to finalize it. In the meantime, something happened that is unique in Europe: César-Pierre Richelet had to produce and to publish his *Dictionnaire françois contenant les mots et les choses* (1680) in Switzerland, because the privilege of the *Académie* prohibited the publication of lexicographical ideas and works in France between 1674 and 1714. His was the first dictionary whose definitions were entirely monolingual. The book is highly praised because of its elaborate system of marking codes and registers. Lexemes are distinguished as being used in certain professions and situations, as being archaic or of foreign origin, as having certain connotations or being restricted to certain types of text, as exclusively oral, and in other respects. Richelet, who was professor of French as a foreign language, was eager to ensure the correct use of the language by foreigners.

The ambitions of the official dictionary of the *Académie* are well known. Its main interests are the purity of the language and the *bon usage*, although the rigorousness with which these aims were followed has been overstated. Archaic words just like technical terms, vulgar words, and neologisms were, however, banned. The preface of the 1694 edition states as objectives "la Langue commune, telle qu'elle est dans le commerce ordinaire des honnestes gens, & telle que les Orateurs et les Poétes l'employent" (after Bray, 1990, 1799). Contrary to the dictionaries of the Italian and Spanish academies, the French one did not give any quotations or sample texts. The definitions rest solely on the intuition of the academicians.

Simultaneous with this French development, the language raised and found much interest outside the country. Its appearance in the usual multilingual dictionaries and textbooks is ample proof. In addition, bilingual works appeared outside the country, which show the influence of French, together with Italian and Spanish, on the European scene.

The German path from Latin glosses to the first monolingual exhaustive dictionary of the language (Johann Christoph Adelung: *Versuch eines vollständigen grammatisch-kritischen Wörterbuches Der Hochdeutschen Mundart*, 1774–1786) was extremely

long. Outstanding in the wake of the glossaries and early Latin–German dictionaries was, after 1400, the *Vocabularius ex quo*, a Latin–German dictionary with grammatical markings that grew from a rather slender first version into a voluminous work and whose German interpretations, taken as a whole, are a full-size thesaurus of Early Middle High German vocabulary. With 270 manuscripts extant today, it held its unrivalled position for some 50 years. Nevertheless, its intention was to support the reading of Latin texts. Different in this respect, though still a Latin–German dictionary, is Johannes Melber's *Vocabularius praedicantium* (1477–1480), which complements its Latin lemmata with a wealth of rhetorically chosen synonyms in order to help German preachers write their sermons in the vernacular. At the same time, Gerd van der Schueren started his *Theutonista vulgariter dicendo Duytschlender* (1488) with a Low-German and Latin part (to be followed by a Latin and Low-German one) with the obvious intention of organizing his dictionary according to German lemmata. It was the first time that the concept of 'mother tongue' made itself felt in German lexicography.

In the spirit of Humanism, which cultivated classical Latin but also the national vernaculars, dictionaries appeared that made Latin the translation of German (for example, Josua Maaler, *Teütsch Spraach*, 1561) and not the other way round. Moreover, German played its part in many multilingual works (like Hadrianus Junius' *Nomenclator omnium rerum*, 1567) that stabilized the vernaculars against Latin (and Greek) by quoting the most influential European languages side by side. Rich as these bilingual dictionaries are, they remain typological hybrids.

Finally, in 1616, Georg Heinisch published *Teütsche Sprache und Weißheit,* the first monolingual German dictionary, which however was unluckily aborted after the letter G. The need to have a comprehensive dictionary of this type was discussed in the so-called *Fruchtbringende Gesellschaft*, a privately founded and organized society of (mostly) noblemen who developed some absurdly baroque ways of communicating with each other. This *Gesellschaft* (which was one among several) fulfilled the function of the respective academies in Italy and France, without being one. Its work was politically motivated. In view of the fact that Germany was not a united nation, it wanted to establish the language as a common bond by documenting it in grammars and dictionaries, stressing that German was a *Hauptsprache*, i.e., a language of prime importance like any other one, in particular like French, which was its great rival at that time. The leading spirits in this discussion were Christian Gueintz, who published a grammar, Georg Philipp Harsdörffer with his work on practical philology and poetics, the lexicographer Caspar Stieler, and, above all, Justus Georg(ius) Schottel(ius), the author of the most influential book *Ausführliche Arbeit von der Teutschen HaubtSprache* (1663). It combined general linguistic aspects with a complex grammar. Lexicographically, all these authors favored the principle of the *Stammwort* (root word). According to this principle, dictionaries were to list root words, then all derivations and compounds that the German language could generate from them. This feature was supposed to be its outstanding one. Outside the *Sprachgesellschaften,* it was the philosopher Gottfried Wilhelm Leibniz who advocated the compilation of a German dictionary.

Almost absurd is the fact that the result of this discussion was a bilingual dictionary again, *Das herrlisch Grosse Teutsch-Italiänische Dictionarium* von Matthias Kramer (1700, important 2nd edn., 1702). Meant to serve the needs of foreign language teaching, it excelled in the way in which the German vocabulary was documented. The aim of the authoritative comprehensive German dictionary for Germans was only achieved in the course of the 18th century.

For a long time, English speakers thought of their own language as uneloquent, inadequate, and misspelled. During the reign of Elizabeth I and Henry VIII, this verdict slowly gave way to a more positive judgment, inspired not only by Elizabethan literature, but also by many translations from the classical languages and by a special culture of rhetoric. Lexicography developed from glossaries to Latin–English and English–Latin dictionaries; terminological treatises made the special English vocabulary of seafaring, agriculture, and other crafts available. The transition to monolingual English dictionaries was made easily and smoothly towards the end of the 16th century.

After 1500, English lexis was shaped by a massive influx of words from other languages, in particular from French and, via French, from Latin. With the additional help of the structural possibilities of word formation, a plethora of new words and hybrids from old words came into being that were hard to understand for those who knew nothing but their English as it was inherited from Germanic stock (and early latinizations, which nobody recognized as such). Of course, the acceptability of these lexical innovations was debated – and in most cases judged in a pragmatic way. They were thought to be acceptable where they filled a semantic gap in the indigenous language. The need arose to make their own language intelligible to semi-educated people. Monolingual, so-called hard word, dictionaries were the adequate remedy.

Actually, they were camouflaged bilingual dictionaries because they bridged the two linguistic worlds, the Germanic and the Latin one, which English then consisted of (and, to a certain extent, still consists of today). The lexicographical technique was taken from the current English–Latin forerunners, such as the *Promptorium parvulorum* (1499), the *Catholicon anglicum* (ms. 1483), and Richard Huloet's *Abecedarium anglicolatinum* (1552). It was plain synonymy, one 'hard' English word explained by a well-known one or by a plain statement. These hard word dictionaries were didactic projects rather than scientific ones. William Bullokar appended a list of hard words to his grammar (*The First Part of the Elementarie*, 1582), without, however, 'translating' them. Edmund Coote included a list of 1,500 in his highly successful *The English Schoolmaister* (1596), all semanticized by one synonym. In 1604, Robert Cawdrey published his *Table Alphabeticall, conteyning and teaching the true writing, and vnderstanding of hard vsuall English words* [...]. There then followed the dictionaries of John Bullokar (*An English Expositor*, 1616), Henry Cockeram (*The English Dictionarie*, 1623), Thomas Blount (*Glossographia*, 1656), Edmund Phillips (*The New World of Words*, 1658), Elisha Coles (*The Compleat English Schoolmaster*, 1674), and J[ohn] K[ersey], *A new English Dictionary*, 1702). As is almost natural, a gradual development took place. The number of entries grew steadily up to 25,000; domains of interest shifted from the general to the specific, old words, rare words, names were gradually included. The full range of a general monolingual dictionary was reached by the beginning of the new century with Nathanael Bailey's *Universal Etymological English Dictionary* (1721). According to the elaborate title, the author planned to give "the derivations of the generality of words in the English tongue," "a brief and clear explication of all difficult words," "a large collection and explication of words and phrases," and "a collection of our most common proverbs." There are some 40 000 entries.

The appearance of vernacular dictionaries in England was almost free of the ideological and national overtones that are to be found in the other European countries. Some English authors demanded that an academy be founded that was to rule on the language like the French one. Among them were John Dryden, John Evelyn, Daniel Defoe, and Jonathan Swift. They were not successful. It was Dr Samuel Johnson's famous *Dictionary of the English Language* (1755) that, eventually, fulfilled this function. For English speakers, it has long served as the model of a monolingual dictionary of their own language. What other nations did with the help of official institutions, the English did within the framework of a private initiative.

Verner's Law

J Bourns, Harvard University, Cambridge, MA, USA

© 2006 Elsevier Ltd. All rights reserved.

Among the most dramatic achievements of early Indo-European scholarship, the elucidation of Verner's Law (VL) heralded a turning point in the history of the young discipline. This famous sound law owes its discovery to Karl Verner, the Danish scholar whose article of 1877 provided the first principled account of the conditions underlying apparent exceptions to Grimm's Law (GL). Through meticulous analysis and lucid argumentation, Verner brilliantly eliminated one of the most vexing cases of 'irregular' sound change. Hailed as decisive evidence in the main controversy of the day, Verner's insight immediately became the centerpiece of the Neogrammarian argument that sound change operates

Verner's Law

J Bourns, Harvard University, Cambridge, MA, USA

© 2006 Elsevier Ltd. All rights reserved.

Among the most dramatic achievements of early Indo-European scholarship, the elucidation of Verner's Law (VL) heralded a turning point in the history of the young discipline. This famous sound law owes its discovery to Karl Verner, the Danish scholar whose article of 1877 provided the first principled account of the conditions underlying apparent exceptions to Grimm's Law (GL). Through meticulous analysis and lucid argumentation, Verner brilliantly eliminated one of the most vexing cases of 'irregular' sound change. Hailed as decisive evidence in the main controversy of the day, Verner's insight immediately became the centerpiece of the Neogrammarian argument that sound change operates

'blindly' and does not admit exceptions. Above all, Verner's approach exemplified the explanatory power afforded by scientific rigor, thereby setting a high standard for research to come.

According to part of GL, the pre-PGmc voiceless stops **p*, **t*, **k* (< PIE **k*, **k̂*), **k*^{w} give the PGmc voiceless fricatives **f*, **þ*, **χ*, **χ*^{w}. In word-initial position, these reflexes are consistent and basically uncontroversial. Similarly, in noninitial position, Germanic often displays the expected outcomes:

Go. *hafjiþ*, OE *hef(e)ð* 'lifts' : Lat. *capit* 'takes'
Go. *brōþar*, OE *brōðor* 'brother' : Lat. *frāter*, Gk. *phrátēr*, Skt. *bhrātā*
Go. *wairþan*, OE *weorðan* 'become' : Lat. *uertit*, Skt. *vartate* 'turns'
Go. *tiuhiþ*, OHG *ziuhit* 'pulls, draws' : Lat. *dūcit* 'leads'

These forms reflect Gmc **f*, **þ*, **χ* (> **h*) < **p*, **t*, **k*, as predicted.

In other cases, however, the pre-PGmc voiceless stops seem to give *voiced* reflexes:

Go. *uf-habaiþ* 'lifts up' : Lat. *sus-cipit* 'takes up'
Go. *fadar, OE fæder* 'father' : Lat. *pater*, Gk. *patḗr*, Skt. *pitā*
OE *we wurdon* 'we became' : Lat. *uertimus*, Skt. *vāvr̥tima* 'we turned'
OHG *gizogan* 'pulled up, drawn' (ptcp.) : Lat. *ductus* 'led' (ptcp.)

As a comparison with the set above shows, these words reflect Gmc **ƀ*, **đ*, **ǥ* instead of the predicted **f*, **þ*, **χ* (> **h*), thus corresponding to the voiced fricatives **ƀ*, **đ*, **ǥ* resulting from PIE **b*^{h}, **d*^{h}, **g*^{h} by part of GL.

Especially striking are the last two examples in each of the groups above in which 'regular' and 'irregular' outcomes are distributed predictably among different inflectional forms of the same verb. A comparison of further strong verbs in Germanic confirms that when the root of a Proto-Germanic verb ends in a voiceless fricative in the infinitive, the present tense, and the preterite singular, a voiced fricative is found in the preterite plural and the past participle (see Table 1).

The examples in Table 2 reveal that *-s-* and *-r-* participate in the same pattern. Comparative evidence confirms that the *-r-* of OE and OHG goes back to a Gmc **-z-*, which occurs here instead of the expected **-s-*.

In descriptive terms, then, the rule is that voiceless fricatives are replaced by voiced fricatives in the third and fourth principal parts of strong verbs. In the German philological tradition this alternation became known as *grammatischer Wechsel* ('grammatical change'), a designation later borrowed by English.

Table 1 Strong verbs in Germanic

	Infinitive	*Pret.first person sing.*	*Pret.first person pl.*	*Past ptcp.*	
OE	*weorðan*	*wearð*	*wurdon*	*worden*	'become'
OE	*snīðan*	*snāð*	*snidon*	*sniden*	'cut'
OE	*tēon* (< **teohan*)	*tēah*	*tugon*	*togen*	'pull'
(= OHG	*ziohan*	*zōh*	*zugum*	*gi-zogan*	″)
OHG	*līhan* (<* -*h*^{w}-)	*lēh* (< * -*h*^{w}-)	*liwum* (< * -*ǥ*^{w}-)	*gi-liwan* (<* -*ǥ*^{w}-)	'lend'

For decades, the apparently unconditioned dual outcomes of pre-PGmc **p*, **t*, **k*, **k*^{w}, and **s* were taken as indisputable evidence that sound changes like GL reflected mere tendencies and nothing more. Even as further sound laws were discovered and independent evidence for the regularity of sound change accumulated, it seemed inconceivable that a principled explanation could account for the glaring exceptions to GL.

The crucial insight was made by Karl Verner, who observed a correlation between the Germanic facts and the position of the accent in Vedic Sanskrit. Verner noted that, where the Vedic accent directly preceded a voiceless stop, that stop corresponded to a voiceless fricative in Germanic, as predicted by GL. Where the Vedic accent followed a voiceless stop, however, this stop appeared in Germanic as a voiced fricative. Greek comparanda tended to validate this insight:

Go. *brōþar* : Ved. *bhrā́tā* : Gk. *phrā́tēr*; but
Go. *fadar* : Ved. *pitā́* : Gk. *patḗr*

Decisive proof lay in the accentuation of Vedic verbal forms, which, as Verner showed, correlated precisely with the *grammatischer Wechsel* displayed by Germanic strong verbs. Where Vedic presents correspond in stem formation to Germanic presents, the root syllable is accented. In the Vedic perfect, which corresponds to the Germanic preterite, the accent falls on the root in the singular, but on the personal endings in the plural; the Vedic perfect middle participle in *-āná-* is accented on the suffix. The accentual pattern of Vedic may be seen in the following forms of *vr̥t-* 'turn' and *juṣ-* 'enjoy,' the cognates of OE *weorðan* and *cēosan*, respectively (see Table 3).

In attested Germanic languages, the accent is fixed on the root syllable, as it still is in the native part of the English lexicon. Yet, as Verner realized, the Germanic situation did not necessarily reflect the accentual system inherited from PIE. He therefore assumed the following:

Table 2 Germanic strong verbs with *-s-* and *-r-*

	Infinitive	*Pret.first person sing.*	*Pret.first person pl.*	*Past ptcp.*	
OE	*cēosan*	*cēas*	*curon*	*coren*	'choose'
(= OHG	*kiosan*	*kōs*	*kurum*	*gi-koran*	″)
OE		*wæs*	*wǣron*	—	'was/ were'
OHG		*was*	*wārum*	—	″ ″

- The Vedic accent, which could in principle fall on any syllable of the phonological word, faithfully reflects the PIE situation. The accentuation system of PIE was inherited into pre-PGmc.
- At some point *after* the shift of **p*, **t*, **k*, **k^w* to **f*, **þ*, **χ*, **χ^w* by GL, all word-internal voiceless fricatives as well as the sibilant **s* were voiced when the closest preceding syllabic segment did not bear the accent. This sound change is known as Verner's Law. This development generated new instances of **ƀ*, **đ*, **ɡ*, **ɡ^w*, which merged with the **ƀ*, **đ*, **ɡ*, **ɡ^w* resulting from part of GL.
- Following the operation of VL, the movable accent inherited from PIE was replaced by the later Germanic system of fixed root stress.

As a result of Grimm's and Verner's Laws, the obstruent system of early Proto-Germanic comprised far more fricatives than stops, an unnatural distribution from a typological perspective. Later changes served to repair this asymmetry, in particular the development of voiced fricatives to stops in certain environments. Before the dialectal breakup of Proto-Germanic, **ƀ*, **đ*, **ɡ*, **ɡ^w* had already developed to **b*, **d*, **g*, **g^w* after nasals, and **ƀ* and **đ* had probably become **b* and **d* word-initially as well. In the dialectal period, PGmc **z* regularly became **r* in most Germanic languages.

Interesting relic forms confirm that VL also applied to underlying word-initial fricatives when these occurred in intervocalic position after a composition vowel or reduplicated syllable; for example, OHG *mezzirahs* 'Messer, knife' < PGmc **mati-zaχsa-* < **-sókso-* or **-soksó-* (cf. OHG *mezzisahs*, OE *meteseax*, with analogical *-s-* after the simplex **saχsa-*); OIcel *sera* 'I sowed' < PGmc **se-zō* < PIE **se-sóh$_1$-h$_2$e*.

Although Gothic was generally quite conservative in its treatment of the Germanic consonant system, expected VL outcomes were much obscured by inner-Gothic developments. In the principal parts of Gothic strong verbs, analogical remodeling all but neutralized the inherited *grammatischer Wechsel* in favor of the voiceless fricatives of the present tense; cf. OE *drēosan, drēas, druron, droren* 'fall': Go. *driusan*, *draus*, *drusun*, **drusans*; OE *snīðan, snāð, snidon, sniden* 'cut': Go. *sneiþan*, *snaiþ*, **sniþun*, *sniþans* '(cut), harvest.' Verner effects were also undone by so-called *Auslautsverhärtung* (devoicing word-finally and before final *-s*); cf. Go. *dauþs* 'dead,' gen. *daudis* (*-d-* = /đ/). The full picture of VL in Gothic is far more complex; a valuable, thoroughgoing investigation of the problem may be found in Berhardsson (2001).

Table 3 Accentual pattern of Vedic

Pres. third person sing.	*Perf. first person sing.*	*Perf. first person pl.*	*Perf. mid. ptcp.*
vártate	*vavárta*	*vavr̥tmá*	*vāvr̥tāná-*
jóṣate	*jujóṣa*	*jujuṣmá*	*jujuṣāṇá-*

The past several decades have seen significant advances in our understanding of Indo-European accent and ablaut patterns, with VL effects helping identify mobile paradigms and derivational processes associated with the proto-language. Important recent scholarship has demonstrated the diagnostic value of *grammatischer Wechsel* in recovering the underlying inflection and derivational history of Germanic nominal forms, as the following forms illustrate:

- Proterokinetic inflection; for example, strong stem PIE **pér-tu-* m. 'passage, crossing' (> PGmc **ferþ/đu-* > OIcel *fjǫrðr* m., Norw. *fjord*) : weak stem PIE **pr̥-téu̯-* (> PGmc **furđu-* > OE *ford* m. 'shallow crossing'); PIE *ǵénh$_1$-ti-* f. 'birth, origin' (> Gk. *génesis*, Lat. *gēns*) : *ǵn̥h$_1$-téi̯-* (> PGmc **kundi-* > OE *gecynd* n. 'kind, nature')
- Amphikinetic inflection; for example, strong stem PIE **ḱáso-n-* m. 'gray one' (> PGmc **χasan-* > OHG *haso*, NHG *Hase*) : weak stem PIE **ḱaso-n-'* (> PGmc **χazan-* > OE *hara*, Engl. *hare*)
- Root-accented singular vs. suffix-accented collective plural; for example, pre-PGmc **pélth$_2$o-* n. > PGmc **felþa-* n. 'field, expanse' (> OHG *feld* n. 'field') : pre-PGmc **pl̥th$_2$áh$_2$-* > PGmc **fuldōn-* f. 'earth, ground, land' (> OE *folde* f. 'earth')
- Substantivization by accent shift of the type Gk. *leukós* 'white' → *leûkos* 'whitefish'; cf. PIE **b^{h}orsó-*'stiff, erect' (> PGmc. **ƀarza-* > OHG (Bav.) *parr* 'erectus') → **b^{h}órso-* m. 'bristled one' (> PGmc **ƀarsa-* m. > OHG *bars*, OE *bærs* m., Engl. *bass*).

Detailed, insightful surveys of the Germanic material are presented in Schaffner (2001, 2003).

Vietnam: Language Situation

D H Nguyen

© 2006 Elsevier Ltd. All rights reserved.

This article is reproduced from the previous edition, volume 9, pp. 4932–4933, © 1994, Elsevier Ltd.

Vietnam is the crossroads of many civilizations. In addition to the majority language spoken by the ethnic Vietnamese (who call themselves *người Việt*, *người kinh*), there are 53 ethnic minorities. The languages of Vietnam have been classified into four major families.

Language Families

Austroasiatic Languages

This family (ca. 51 184 000 speakers) makes up over 97% of the population and comprises 36 nationalities belonging to five different language groups:

1. The Viet–Mường group (ca. 46 776 000 speakers) makes up 88% of the population and four nationalities – Vietnamese, Mường, Thổ, and Chứt. The 686 082 speakers of Mường are spread over north and central Vietnam (provinces of Hà Sơn Binh, Sơn-la, Vĩnh-Phú, Hoàng-liên-sơn, etc). Thổ is spoken by over 24 000 people in Thanh-hoá and Nghê-tĩnh provinces, and Chứt counts almost 3000 speakers.
2. The Mon-Khmer group (over 1 300 000 speakers) makes up 2.4% of the population and 21 ethnic minorities – Khmer (Cambodian), Bahnar, Sedang, Kơho, Hrê, Mnong, Stieng, Bru, Khmu, Katu, Taoi, Ma, Co, Jeh, Sinmun, Chrau, Mảng, Kháng, Rmam, Brau, and Ơdu. Of the total number (717 291) of Khmer speakers, 297 862 live in Hậu-giang province. The remainder are highlanders formerly referred to as 'montagnards' of Central Vietnam.
3. The Miao-Yao group (760 040 speakers) makes up 1.5% of the population and is composed of three minority languages – Hmong (Miao = Mèo), Mien (Yao = Mán), and Pà-thẻn – spoken primarily in mountain areas of north and central Vietnam.
4. The Tay-Thai group (2 344 000 speakers) makes up 4.4% of the population and is composed of eight minority languages – Tày (901 802 speakers spread over 23 provinces, with Cao-bằng as their main habitat), Thái (766 720 speakers scattered over seven provinces, especially Sơn-la), Nùng (559 702 speakers scattered over 12 provinces, including Lạng-sơn), San Chay (77 104 speakers, nearly half of them in Hà-tuyên), Jeh (27 913 speakers in Hà-tuyên, Lai-châu, and Hoàng-liên-sơn), Lao, Lụ, and Bo-Y.
5. The Kadai group (over 12 000 speakers) consists of Lachi, Laha, Co-lao, and Pu Péo, the latter subgroup having only 300 speakers.

Austronesian Languages

This group, formerly called Malayo–Polynesian, counts 467 000 speakers (0.9% of the population) and is composed of five 'montagnard' languages – Jarai, Rhade, Cham, Roglai, and Chu-ru – among which Cham is spoken in coastal provinces, particularly Thuận-hải province, by descendants of the ancient Kingdom of Champa.

Sino–Tibetan Languages

1. The Han or Chinese group (over one million speakers) is composed of Chinese (= Hoa) – it is the most important minority language, spoken all over the country and numbering 475 739 speakers in Saigon alone – Sán Dìu and Ngái.
2. The Tibeto–Burman group (over 20 000 speakers) is composed of six minority languages – Hani, Phù

4. The Tay-Thai group (2 344 000 speakers) makes up 4.4% of the population and is composed of eight minority languages – Tày (901 802 speakers spread over 23 provinces, with Cao-bằng as their main habitat), Thái (766 720 speakers scattered over seven provinces, especially Sơn-la), Nùng (559 702 speakers scattered over 12 provinces, including Lạng-sơn), San Chay (77 104 speakers, nearly half of them in Hà-tuyên), Jeh (27 913 speakers in Hà-tuyên, Lai-châu, and Hoàng-liên-sơn), Lao, Lụ, and Bo-Y.
5. The Kadai group (over 12 000 speakers) consists of Lachi, Laha, Co-lao, and Pu Péo, the latter subgroup having only 300 speakers.

Austronesian Languages

This group, formerly called Malayo–Polynesian, counts 467 000 speakers (0.9% of the population) and is composed of five 'montagnard' languages – Jarai, Rhade, Cham, Roglai, and Chu-ru – among which Cham is spoken in coastal provinces, particularly Thuận-hải province, by descendants of the ancient Kingdom of Champa.

Sino–Tibetan Languages

1. The Han or Chinese group (over one million speakers) is composed of Chinese (= Hoa) – it is the most important minority language, spoken all over the country and numbering 475 739 speakers in Saigon alone – Sán Dìu and Ngái.
2. The Tibeto–Burman group (over 20 000 speakers) is composed of six minority languages – Hani, Phù

Lá, Lahu, Lolo, Cống, and Sila, the latter two counting less than a thousand speakers.

Ten nationalities (Thai, Tay–Nung, and Mường in the north, Cham and Khmer in southern central Vietnam, and Kỏho, Rhade, Bahnar, and Jarai in the Vietnam Cordillers and the Central Highlands) have their own scripts, some of which were contributed by French missionaries and administrators, and later modified by linguists and literacy workers from the United States as well as by native linguistic scholars.

The official language policy of Vietnam has been:

> to respect the right of minorities of freely use and develop their mother tongues, to lead the struggle by minority people to demand the right to use their mother tongues in cultural and social life, especially in education, and to help them attain conditions favorable to the development of their own languages and the creation of their own writing systems.
> (Hông Giao, 1970: 7)

Between 1957 and 1975, members of the Summer Institute of Linguistics, authorized to work in South Vietnam, helped create Latin scripts and write elementary-level bilingual textbooks for 15 minority languages (Bru, Sedang, Cham, Koho, Bahnar, etc.). Books in the Roman script – based on the Vietnamese *quốc-ngưũ* writing system – as well as elementary-level textbooks have also been printed for Cua, Hroi, Nung, and Thai. The content of these publications is designed 'to disseminate the New Testament of the Protestant Church, to guide people in the civilized lifestyle' (Trần Đức Cường, 1984: 72). Joint research projects by Vietnamese–Soviet teams of linguists in 1979 and 1981 have resulted in monographs on Khmer, Cham, Mường, Laha, Hmong, etc. (Solncey and Hoàng Tuệ, 1984: 3–8).

Historical Origins

The Vietnamese are thought to be descended from a precursor people who once dwelled near the Viet-Lao border of Central and Northcentral Vietnam where today are still found Vietic groups such as the Mu'ò'ng, Nguồn, Arem, Rục, Pọng, Arem, Mày, Sách, Mã Liềng, and Thà Vụ'ng (Nguyễn Tài Cẩn, 1995), (Ferlus, 1979, 1982, 1991, 1996, 1997). Long ago some of these groups moved north into the Red River Valley, lived under their own Hùng Vu'o'ng kings, and then allied with the indigenous Tày ethnicities in the joint Tày-Viet Kingdom of Âu-Lạc at Cổ Loa Citadel near Hanoi (257 to 208 B.C.). This lineage ended when the First Emperor of China and builder of the Great Wall dispatched the Chinese general 趙佗 Zhào Tuó (in *Hanyu Pingyin* transcription) or Triệu Đà (in Vietnamese), who conquered Âu-Lạc and introduced 100 000 soldiers, Chinese rule, Chinese character writing or 字漢 *Chũ' Hán* 'Han (Chinese) script', and the Mandarin administrative system.

Vietnam remained a Chinese province until A.D. 939. After the Chinese departed, the Vietnamese continued the practice of borrowing from the Chinese cultural lexicon as well as structural and grammatical forms, and continued developing the character script, which was then renamed 字儒 *Chũ' Nho* or 'learned script', and which contrasted with newly created characters used for writing purely Vietnamese lexical items. This new demotic script was called 字喃 *Chũ' Nôm* 'southern, local, vernacular script' or simply *Nôm*, which was clearly in evidence by the 13th century, but was perhaps in use as early as the 10th century. Consider the following examples of strategies used for crafting *Nôm* characters: (1) 乭 *giò'i* 'heaven, sky' from Chinese 天 meaning 'heaven' and 上 meaning 'above'; (2) 坦 *đât* 'earth' composed of 土 *thổ* 'earth' for the meaning and 旦, taken from one half of 怛 for the sound *đát*; (3) 魿 *cá* 'fish' is a combination of 魚 'fish' for the meaning and 个 *cá* for the sound; and (4) 巴 *ba* 'three' is composed of the radical 三 meaning 'three' and 巴 *ba* for the sound. These examples show that 10th century Vietnamese were very much aware of the principles used in the construction of Chinese characters, namely to combine a radical part for meaning and a phonetic part for the sound, but the example for *sky*, *heavens* shows that sometimes other methods of creation were used.

Chinese influence in Vietnamese is generally very important and is the result of (1) 1000 years of occupation by Chinese speakers, (2) the role ofChinese as the spoken and written language of administration and, (3) the fact that Chinese continues to be the source of borrowing even today. Chinese loans in contemporary Vietnamese, called Sino-Vietnamese, can make up as much as 80% of the vocabulary in some semantic domains, (Hoàng, 1991: 5). But the depth of Chinese influence extends beyond the lexical. Indeed, some of the typological incongruities of morphology and syntax are now considered to be the result of contact with Chinese and other languages.

Politically independent at last, the Vietnamese then turned their attention to southern rivals, the Champa Kingdom. Three hundred years of greater and lesser hostilities ensued, with ebbs and flows evident in marriage alliances and other accommodations; Vietnamese absorbed some early loans from this source as well. In the 14th century, the Vietnamese gained ultimate control and the boundaries of the language were advanced southward until Vietnam reached its current geographic extension. Chinese *Chũ' Hán* with an admixture of *Chũ' Nôm* writing flourished until the late 1600s when an outside force, Jesuit missionaries including Alexander de Rhodes and Francisco de Pina, developed an orthography based loosely on Portuguese and on Italian models that were intended not for the court but for believers among the common people. It was a romanized script with diacritics for tones and vowels, called *Chũ' Quốc* Ngũ', whose timeline can be sketched as follows: 1620–1631 embryonic beginnings, 1631–1648 revisions, 1651–1659 dissemination, and 1772–1838 finalizing stage, (Lý, 1999: 234–5). Over the 18th and 19th centuries, official character script and popular roman script co-existed, but gradually *Chũ' Quốc Ngũ'*, aided first by French colonial proclivities in favor of a Latin-based script and the Church and later by populist movements, led to a shift in orthography; the character-based writing of Vietnamese was finished entirely by 1917 when the French eliminated the Chinese examination system, cf., Alexandre de Rhodes (1651) and Nguyễn Đình Hoà (1973, 1992).

Regional Varieties

The regional varieties of Vietnamese are divided into three main types: Northern (e.g., Hanoi), Central (e.g., Huế), and Southern (e.g., Hồ Chí Minh City). Recently, it has been suggested by Ferlus and Nguyễn Tài Cẩn that a fourth regional area should be added, Northcentral Vietnam or Area IV (Nghệ An Province), as this

Table 1 Vietnamese tone categories

	Level	*Rising*	*Falling*
High	ngang [ŋaŋ33]	sắc [săk35ˀ]	hỏi [hỏi323]
Low	huyền [huiən 31]	nặng [năŋ21ˀ]	ngã [ŋa4ˀ5]

area preserves several special features lost elsewhere, cf., below and Alves (2000).

Phonological Forms

Vietnamese of the northern type has six tones, the southern type five, and central/northcentral types five or six, all of which can be traced back to a parent tone system of three columns of *level*, *rising*, and *falling* tones and two rows, *high* and *low*. Haudricourt (1954) proposed that Vietnamese was originally not a tonal language but that tonality arose as a part of the historical development of Vietnamese. In this theory syllable-final consonants caused changes of pitch; rising tones were produced in syllables that formerly ended in -p, -t, -k, -ʔ, whereas falling tones were created in syllables that once ended in -s or -h, and mid-level tones were created when syllables possessed no final consonants to draw the pitch up or down. Haudricourt's famous theory of Vietnamese *tonogenesis* explains how a non-tonal Mon-Khmer language could changes its typological features and become tonal. Vietnamese tone categories are also associated with specific voice quality contrasts that accompany each tone, perhaps a residue of its tonogenetic history. Thus the tone called *ngang* demonstrates mid-level with modal voice (tones are notated with the scale-of-five system in which 5 is the highest and 1 is the lowest level, cf. Y. -R. Chao, 1930); *huyền* falls from mid with lax/breathy voice; *sắc* rises sharply from mid with tense voice ending in a glottalized coda; *nặng* falls with increasingly tense voice from early in the syllable to glottal statis; *hỏi* is a fall-rise tone; *ngã* has a glottal interruption in the center of the syllable, sounding almost as if it were composed of two syllables VʔV, with overall a very high rising pitch, cf., Nguyễn and Edmondson (1997). The names *ngang*, *huyền*, etc., illustrate the tone they name. See Table 1.

Vietnamese consonants in Hanoi speech distinguish five places of articulation – *labio-dental*, *denti-alveolar* (the *t* series is denti-alveolar initially and apico-postalveolar finally), *palatal*, *velar*, and *glottal*, and several manners of articulation – *voiceless aspirated stops*, *voiceless unaspirated stops*, *preglottalized voiced stops*, *fricatives* (x is a lamino-prepalatal narrow grooved fricative), *liquids*, and *nasals*. Compare *Chữ' Quốc Ngữ'* and IPA values of these consonants in Table 2.

Table 2 Vietnamese consonant system

ph- [f]	th- [t̪ʰ]		kh- [x]	
-p [ˀp͡]	t [t̪ ˀt͡]		c, k, q- [k]	
		tr-, ch [ʈʂ]		
b- [ˀb]	đ [ˀd]		g(h)- [g] or [ɣ]	
	x-, s- [s]			h-
v- [v]	r-, d-, gi- [z]			
m [m]	n [n]	nh [ɲ]	ng(h) [ŋ]	
	1- [1]			

Table 3 Regional variation of initials from Alves (2000). QN = Quốc Ngữ, NV = Hanoi, NCV = locations in Nghệ An Province, CV = Huế, SV = Hồ Chí Minh City

QN	*NV*	*NCV*	*CV*	*SV*
s	s	ʂ	ʂ	ʂ
x	s	s	s	s
tr	c	ʈr	ʈr	ʈr
ch	c	c	c	c
r	z	r	r	r
d	z	j	j	j
gi	z	z	j	j
v	v	v	j	j
-nh	ɲ	ɲ	n	n
-n	n	n	n/ŋ	n/ŋ
-ng	ɲ	ɲ	ŋ	ŋ
-ch	c	c	t	t
-t	t	t	t/k	t/k
-c	k	k	k	k

In southern Vietnamese there are some important differences in initials compared to Hanoi. Notably *tr-* and *s-* are retroflexed [ʈr ʂ] and contrast with *ch-* [ʈɕ] (with very little friction compared to Hanoi speech) and *x* [s] respectively, *g-* [g], *r-* [r] (with a lot of variation in realization of the r-), *v-* [j] (Thompson, 1987: 89) *d-*, *gi-*[j]. As mentioned above, Northcentral Vietnamese has preserved three distinct pronunciations for *d-*, *r-*, and *gi-*. See Table 3.

Vietnamese word structure allows only sequences $C_1V(V)C_2$, whereby C_1 can be any allowed initial (notice that *p-* cannot be an initial except in words borrowed from French, e.g., *pin* 'battery' and *píp* 'smoking pipe'). The syllable coda C_2 can be *-ˀp͡ -ˀt͡ -ˀc͡/k -ˀc͡h -m -n -nh* [ɲ] *-ng* [ŋ]. One noteworthy phonological change in northern speech is engendered by these final consonants. Whenever the velars *-c* or *-ng* follow back rounded vowels *u*, *ô*, or *o*, there is *double closure*, and a velar and labial are simultaneously formed (because these are also accompanied by glottal stop, in reality they are triply closed). The preceding round vowel causes simultaneous assimilatory rounding of [-k -ŋ] to [-k͡p -ŋ͡m] in addition to

Table 4 Vietnamese rhymes with nuclear vowel(s) in the left column and codas in rows. Compiled from Lế Vắn Lý (1948), Haudricourt (1951), Gordina (1960), Emeneau (1951), as reported in Cao Xuân Hạo (2003: 88–103)

	Ø	*j* *-i/y*	*w* *-o/u*	*m* *-m*	*p* *-p*	*n* *-n*	*t* *-t*	*ɲ* *-nh*	*c* *-ch*	*r* *-ng*	*k* *-c*

iə	ia	-	iêu	iêm	iêp	iên	iêt	-	-	-	-
e	ê	-	êu	êm	êp	ên	êt	-	-	-	-
ɛ	e	-	eo	em	ep	en	et	-	-	-	-
ɛː	e	-	-	-	-	-	-	-	-	eng	ec
ɯ	u'	u'i	u'u	-	-	-	u't	-	-	u'ng	u'c
ɯʌ	u'a	u'o'i	u'ou	u'om	u'op	u'on	u'ot	-	-	u'ong	u'oc
ɣ	-	ây	âu	âm	âp	ân	ât	-	-	âng	âc
ɣː	o'	o'i	-	o'm	o'p	o'n	o't	-	-	-	-
a	-	ay	au	ăm	ăp	ăn	ăt	anh	ach	ăng	ăc
aː	a	ai	ao	am	ap	an	at	-	-	ang	ac
u	u	ui	-	um	up	un	ut	-	-	ung	uc
uʌ	ua	uôi	-	uôm	-	uôn	uôt	-	-	uông	uô
o	ô	ôi	-	ôm	ôp	ôn	ôt	-	-	ông	ôc
ɔ	o	oi	-	om	op	on	ot	-	-	ong	oc
oː	-	-	-	-	-	-	-	-	-	ôông	-
ɔː	-	-	-	-	-	-	-	-	-	oong	ooc

diphthongization of the vowel, e.g., *dùng* 'to use' [zᵘʊ͡ŋm̩31̤] *dục* a suffix [zᵘʊ͡kp̰21̰ˀ], *học* 'study, -ology' [haᵘ͡kp̰21̰ˀ] and *đồng* 'Vietnamese piastre' [ˀɗɣᵘ͡ŋm̩31̤]. Similarly, whenever the palatals *-ch* or *-nh* follow the unrounded vowels *-i*, *-ê*, or *-a*, then diphthongization occurs as before, but there is no rounding, as all segments are unrounded to begin with, e.g., *minh* 'clear, bright' [miⁱŋ33], *thích* 'to like' [thiⁱc35ˀ], *lệnh* 'order, command' [ləⁱɲ21̰ˀ], *ếch* 'frog' [əⁱc35ˀ], *anh* 'Sir, you, older brother' [ɜⁱŋ33] and *thạch* 'stone' [thɜⁱc21̰ˀ].

The rhymes of Vietnamese syllables can have the nuclear vowels: / i iə e ɛ ɛː ɯ ɯʌ ɣ ɣː a aː u uʌ oː o ɔː ɔ/. If one assumes that /iə ɯʌ ɯʌ uʌ/ function as the long versions of /i ɯɯ u/, then all vowels except /e/ have long and short forms. In Table 4 one sees the possible combinations of these nuclear vowels with the set of possible codas. Nuclear vowels may occur in open syllables, i.e., with -ø coda or in one of the following combinations: -j (graphically -i/-y), w (graphically -o/-u), -m, -p, -n, -t, -nh, -ch, -ng, -c. There are some notable areas where combinations are disallowed. For example, there are no rhymes *ij, *uw, or *ow, palatal coda may combine only with -a- and -i-, and velars may not combine with high front vowels except /ɛː/.

Word Category and Constructions

Contrary to some reports, Vietnamese is not an absolutely monosyllabic language, but one with many compounds and reduplicated structures. Compounds demonstrate disyllabic construction and have either been borrowed intact from Chinese (so nouns are right-headed, e.g., *cổ đại* [old-[era$_N$]$_N$] 'antiquity', *thanh âm* [voice-[sound$_N$]$_N$] 'sound', and verbs are left-headed *ẩu thổ* [$_V$[$_V$ vomit]-spit] 'to vomit') or are pure Vietnamese creations of Vietnamese or mixed lexical roots, all left-headed *ngù'o'i Việt* [$_N$[$_N$ people]- Viet] 'Vietnamese people', *nhà thu'o'ng* [$_N$[$_N$ house]-of the injured] 'hospital', *làm việc* [$_V$[$_V$ do]-work] 'to work', except for the group of *father-mother compounds*, which consist mostly of semantically paired things, e.g., *bố mẹ* father-mother 'parents', *bàn ghế* table-chair 'furniture', *bát dĩa* bowl-plate 'dishes', which function as a unit without head. Vietnamese reduplicatives are also very productive, such as *complete reduplicatives* having the same onset and rhymes, *cu'ò'i-cu'ò'i* 'laugh a little', *nói nói* 'keep talking', *register change reduplicatives* with the repeated part, be it on the right or left, having opposing high-low register of the same tone class, e.g., *xẹp* 'be flattened' vs. *xép-xẹp* 'be completely flattened' (with a sắc tone syllable being here followed by a nặng reduplicant); some have vowel changes in the reduplicant, e.g., *hốc* 'hole, hollow' vs. *hốc-hác* 'be emaciated, gaunt'; some can have changes of onset in the first element and some in the second element as *rộn* 'be noisy' vs. *chộn-rộn* 'be agitated' and *xẹp* 'beflattened' vs. *xẹp-lép* 'be completely flattened', (Thompson, 1987).

Regarding word categories, Vietnamese has the following: nouns *Lê Quý Đôn* 18th century author, *học sinh* 'student', *gà* 'chicken'; classifiers *hai con chó* two-CLS-dog 'two dogs', *các cái bàn* plural-CLS-table 'tables'; locatives *ngoài* 'outside', *bắc* 'north'; numerals *hai* 'two', *ba* 'three'; verbs *đi* 'to go, walk', *nói* 'to talk'; stative verbs (adjectives) *tốt* 'good', *mó'i* 'new'; and pronouns. It is noteworthy for its rich and

complex set of pronouns. There are personal pronouns *tôi* 'I, me (with modesty, servant)', *ta* 'I (emphatic), one', *tao* 'I (arrogant)', *mày, mi, bay* 'you (arrogant)', and nó 'it (animal)' or 'he (for children or contemptible persons, criminals)'. The term *mình*, meaning 'body' is used for 'you (intimate)'. The term *chúng* 'group of animate objects' can be combined with the above to make plurals such as *chúng tôi* 'we-exclusive' and *chúng ta* 'we-inclusive'. In public discourse, kinship names are often used, e.g., *chị* 'older sister, you-Ms.', *bà* 'grandmother, old woman, you-Madame', *anh* 'older brother you-Sir', *cháu* 'niece/nephew, grandchild, you-Young Person', *cô* 'father's sister, you-Ms.' (One speaker from Hanoi said that *cô* was obligatory to address one's female teachers.) These can become like 3rd person pronouns by adding *ấy*, e.g., *anh ấy* 'he, that Sir (a contemporary)', *chị ấy* 'she, that Ms. (a contemporary)', but there is also *nó* 'he (deprecating)' and *họ* 'they'. Kinship names also have features of anaphoric nouns, they contain additional information about gender and degree of familiarity, and they function differently in tracking participants in discourse.

Phrases and Sentences

Phrases are mostly left-headed, e.g., attributive adjectives follow heads, *đồng Việt Nam* piaster-Vietnam 'the Vietnamese piaster', complements follow heads, *ăn co'm* eat-rice 'to eat (food)', whereas adverb-like elements can appear to the left or right of the head, *rất đắt* very-expensive 'very expensive' but *đắt lắm* expensive-very 'very expensive'.

Sentences tend to have known, presupposed information at the beginning and new, asserted information at the end. One manifestation of this principle is that after introducing a referent, a close-knit group of clauses or a topic chain follows whose subjects are PRO, the zero pronoun. For example in the famous story about Bần with no overt pronouns, one finds:

Bần chỉ là một anh nghèo xác, e_i ngày ngày lang thang khắp xóm này khác e_i xin ăn. *Bần$_i$ just be a person poor, e$_i$ day-day wandered all over hamlet this different e$_i$ beg eat* 'Bần was a poor fellow [who] day after day wandered about from one place to another begging for food.'

Sources and Conclusion

There are several worthy examples of grammars and dictionaries of Vietnamese. For the English speaker, there is Nguyễn Đình Hoà (1997) grammar, which is richly exemplified, but reflects the spelling and sometimes the usage before 1975. Thompson (1965, 1987), written in the 1960s, also has a lot of examples, but employs a structuralist model of grammar that might be difficult for some to understand. Some of the examples are also no longer acceptable to contemporary speakers. Cao Xuân Hạo (2003) in an 800-page collection of his essays has discussed Vietnamese from the phonological, grammatical, and semantic perspectives. His bibliography includes many important scholars from the U.S. western Europe, and Russia, such as Bloomfield, Bybee, Chao Yuen Ren, Chomsky, Ducrot, McCawley *et al.*, and a glossary of linguistic terms with English definitions. Notable dictionaries are those by Nguyễn Đình Hoà in many editions, Bùi Phụng (1995) in many editions, and Viện Ngôn Ngữ' Học (2000), the model for the contemporary language and the standard-setting dictionary from the Linguistics Institute of Vietnam.

Despite the obvious influences of contact, Vietnamese shows a surprising number of unique features (e.g., tense markers for past and future, some right- and some left-headed typological features), arguably the richest set of pronouns in East and Southeast Asia as well as properties typical of the linguistic area (e.g., a fully developed tone-voice quality sound system, a sharply reduced coda inventory, four-syllable elaborate expressions, and a numeral classifier system). Vietnamese is thus ultimately not very similar to Mon-Khmer, cf., Haudricourt (1953), and is certainly not similar to Sinitic, but a language perhaps analogous in its position to Modern English in the sense that it too has lost many features found in related languages. Yet, despite borrowing and shift influences, Vietnamese, like English, remains an independent and distinctive language in its own right.

Viëtor, Wilhelm (1850–1918)

J B Walmsley, Universität Bielefeld, Bielefeld, Germany

© 2006 Elsevier Ltd. All rights reserved.

Wilhelm Viëtor was born on December 25, 1850, and went to school in Cleeberg and Weilburg, Germany. From 1869 to 1872 he studied theology and classical philology at Leipzig, Berlin, and Marburg. He then taught in England from 1872 to 1874, and from 1874 to 1875 he studied for his doctorate in Marburg, after which he taught at various schools in Germany. From 1882 to 1884 he worked as Lecturer in Teutonic Languages in Liverpool and in 1884 was appointed Associate Professor of English Philology at Marburg, where he remained for the rest of his life. He died on September 22, 1918.

The main areas with which Viëtor concerned himself were foreign language teaching (FLT) reform (Viëtor, 1882), philology (Viëtor, 1876), phonetics (Viëtor, 1884), a national standard for German pronunciation, and marrying the philological disciplines with the demands of teacher training (Viëtor, 1902).

Viëtor made his name early with his notorious anonymous publication of 1882. This pamphlet is divided into two major sections. In the first section,

Viëtor, Wilhelm (1850–1918)

J B Walmsley, Universität Bielefeld, Bielefeld, Germany

© 2006 Elsevier Ltd. All rights reserved.

Wilhelm Viëtor was born on December 25, 1850, and went to school in Cleeberg and Weilburg, Germany. From 1869 to 1872 he studied theology and classical philology at Leipzig, Berlin, and Marburg. He then taught in England from 1872 to 1874, and from 1874 to 1875 he studied for his doctorate in Marburg, after which he taught at various schools in Germany. From 1882 to 1884 he worked as Lecturer in Teutonic Languages in Liverpool and in 1884 was appointed Associate Professor of English Philology at Marburg, where he remained for the rest of his life. He died on September 22, 1918.

The main areas with which Viëtor concerned himself were foreign language teaching (FLT) reform (Viëtor, 1882), philology (Viëtor, 1876), phonetics (Viëtor, 1884), a national standard for German pronunciation, and marrying the philological disciplines with the demands of teacher training (Viëtor, 1902).

Viëtor made his name early with his notorious anonymous publication of 1882. This pamphlet is divided into two major sections. In the first section,

'Language,' Viëtor covered the problem of sounds and writing, the tasks of philology, aspects of grammar teaching, and the influence of classical models on the description of modern languages. He remarked caustically that if – on the classical model – the article were to be given four cases, then nouns ought to have six:

1. nominative: Berlin
2. accusative: Berlin
3. genitive: *ab* (or *von*) Berlin
4. dative: *zu* (or *nach*) Berlin
5. locative: *in* Berlin
6. instrumental: *mit* (or *durch*) Berlin.

The second section ('Teaching') dealt with first language pedagogy and the teaching of modern foreign languages and classics. Viëtor argued against the learning of rules and lists for grammar and lexicon. He also pointed out that the role of the text in FLT had become perverted to the point of being simply a means of confirming the syntactic rules just taught.

The functions of the text were taken up again in his discussion of the main principles of FLT (Viëtor, 1902), which cover the language ecology (which languages ought to be taught, and in which order?), the role of phonetic instruction, morphological description (to be based on spoken rather than written forms), the importance of syntactic principles (insight) as opposed to rules, and the nature of the texts to be used.

Viëtor initiated a lengthy process of reform in language teaching in Germany (Hüllen, 1979: 1). Through his connections with other members of the reform movement – Sweet, Passy, and Jespersen – Viëtor helped to determine the shape of FLT in Europe.

The British Virgin Islands are an overseas territory of the United Kingdom with internal self-government, consisting of more than 60 Caribbean islands that are part of the West Indies. Only 16 of the islands are inhabited.

The first settlers of the British Virgin Islands were Arawak Indians, from South America; these were followed by Caribs in the 15th century. Christopher Columbus stopped here on his second trip to the New World and named the islands Las Vírgenes. The first establishments were Spanish copper mines in the 17th century. In the second half of that century, the islands came under Dutch ownership for a short while, with a base on Tortola. The next colonizers were the English, who ousted the Dutch in 1672 and introduced sugar cane plantations and slavery. Thanks to this and to hardworking Quakers who settled here, the islands prospered in the late 18th and early 19th centuries, with an economy based on sugar, cotton, and spices. This period was followed by an economic decline, partly a result of the abolition of slavery in the early 19th century. As a result of economic recession, the population decreased as well after many planters left the islands. In the second half of the 19th century, the islands were incorporated into the British colony of the Leeward Islands. The word 'British' was added to the name at the end of World War I, after the United States purchased the 'Danish West Indies' from

The first settlers of the British Virgin Islands were Arawak Indians, from South America; these were followed by Caribs in the 15th century. Christopher Columbus stopped here on his second trip to the New World and named the islands Las Vírgenes. The first establishments were Spanish copper mines in the 17th century. In the second half of that century, the islands came under Dutch ownership for a short while, with a base on Tortola. The next colonizers were the English, who ousted the Dutch in 1672 and introduced sugar cane plantations and slavery. Thanks to this and to hardworking Quakers who settled here, the islands prospered in the late 18th and early 19th centuries, with an economy based on sugar, cotton, and spices. This period was followed by an economic decline, partly a result of the abolition of slavery in the early 19th century. As a result of economic recession, the population decreased as well after many planters left the islands. In the second half of the 19th century, the islands were incorporated into the British colony of the Leeward Islands. The word 'British' was added to the name at the end of World War I, after the United States purchased the 'Danish West Indies' from

Denmark in 1917 and renamed them the 'U.S. Virgin Islands.' The 1967 constitution gave the islands internal self-government.

The population is 22 187 (July 2004 estimate); 83% are related to the slaves brought from Africa. The rest of the population are of European, Indian, and Asian origin. The official language is English. Other languages spoken are Virgin Islands Creole English, Papiamentu, and Spanish. The literacy rate is 97.8%, according to a 1991 estimate.

The U.S. Virgin Islands are an unincorporated territory of the United States in the Caribbean, West Indies. They comprise the three largest U.S. islands (St John, St Croix, and St Thomas) and 50 small islands next to them. The islands were first spotted by Europeans in the second voyage of Christopher Columbus. The Carib Indians, who were local inhabitants there, resisted the presence of Europeans and as a result were massively killed in the 17th century. Ownership of the islands during that time shifted between Spain, England, France, Holland, and Denmark. The islands' economy was mainly based on sugar and cotton plantations, maintained by slave labor. During the 17th century, the islands were divided between the English and the Danish. The Danes established a permanent colony (Danish West Indies) on St Thomas in the 17th century and on St John in the early 18th century. They later purchased St Croix from the French. By the mid-19th century, slavery was abolished, and the island's economy suffered a serious recession. Danish control of the major islands continued (except for two brief periods of British occupation) until after the first World War, when the United States bought the territory in 1917 for the highest sum of money they had ever paid for land.

The population of the islands is 108 775 (July 2004 estimate). The majority of the population is West Indian (81%), while the rest of the population is mainly from the U.S. mainland (13%) or from Puerto Rico (4%). The official language is English. Virgin Island Creole English, Papiamentu, and Spanish are also used. Dutch Creole (Negerhollands), which flourished at the end of the 18th century is by now extinct.

The question of virtual objects is basically of an ontological nature, but it has direct consequences for the theory of truth and, hence, for the semantics of natural language. Around 1900, a discussion arose about the nature of 'reality' or, in other words, about the question of 'what there is.' Two schools of thought developed, extensionalism and intensionalism. The extensionalists hold that reality and actual existence are the same: Whatever is, exists; there is no being outside existence. For an entity *e* to be said to 'exist,' a few criteria must be satisfied, the most important of which are the following:

1. *e* is subject to the physical laws of causality.
2. *e* is fully defined, in the sense that it has all the properties an entity of that nature is supposed to have – even if not all the values of those properties are known.
3. *e* has a well-defined identity, in that at any time *t* it is identical with itself and distinct from all other entities.
4. *e* cannot both have and lack a given property.

The question of virtual objects is basically of an ontological nature, but it has direct consequences for the theory of truth and, hence, for the semantics of natural language. Around 1900, a discussion arose about the nature of 'reality' or, in other words, about the question of 'what there is.' Two schools of thought developed, extensionalism and intensionalism. The extensionalists hold that reality and actual existence are the same: Whatever is, exists; there is no being outside existence. For an entity *e* to be said to 'exist,' a few criteria must be satisfied, the most important of which are the following:

1. *e* is subject to the physical laws of causality.
2. *e* is fully defined, in the sense that it has all the properties an entity of that nature is supposed to have – even if not all the values of those properties are known.
3. *e* has a well-defined identity, in that at any time *t* it is identical with itself and distinct from all other entities.
4. *e* cannot both have and lack a given property.

Criterion 1 seems self-evident. As regards criterion 2, consider the example of an actually existing man. He was born at a specific time; has breathed a specific number of times since his birth; has a specific weight, blood pressure, shoe size, and so on, even if that information is not always available to everyone. The criteria 2 and 3 are due to the American philosopher Willard V. O. Quine (Quine, 1953). Criterion 4 is known as the Principle of Contradiction and is due to Aristotle: "It is not possible for the same property to adhere and not to adhere to the same entity at the same time and in the same respect" (*Metaphysics* IV, 3, 1005b19).

The intensionalists do not deny the extensionalist's notion of existence, but they maintain that the universe contains more than just existing entities. They differ from the extensionalists mainly in that they accept the reality, but not the existence, of so-called virtual objects. Virtual objects have been thought up by a thinking individual. And, because thinking includes not only the strictly disciplined forms of imagining states of affairs normally found in hypotheses produced in science or by the police, but also all kinds of fantasizing, dreaming, and artistic imagination, virtual objects may fail to satisfy the criteria 1, 3, and 4, and will in any case fail to satisfy criterion 2 because they have only those properties (in virtual form) with which they have been fitted out by the imagination. They lack actual existence, although it may turn out that what has been thought up, perhaps as part of a hypothesis, actually exists – in which case we say that they are *matched* by real-world objects.

The most prominent representative of this philosophy is the German–Austrian philosopher Alexius Meinong (1853–1920). Meinong accepted not only virtual entities, but also 'objects of a higher order' (mostly relational objects such as 'the difference between A and B') and also what are normally called reifications or abstractions, such as 'the prime minister's popularity with the voters' or 'the triangle in general.' Such objects do not exist but they 'subsist' in the sense that they owe their being to the entities that do exist.

Among the virtual objects Meinong distinguished those that happen not to exist although they could have from those that cannot possibly exist, such as a round square. Virtual objects are automatically created by the thinking mind, no matter what properties are mentally assigned to them. Their identity is fixed by the mind. When I think up one man who is both bald and rich, there is one virtual man; but when I think up two men, one bald and one rich, there are two virtual men.

Thinking is by definition the setting up of a virtual world, and so is speaking, in so far as speaking is an expression of thought. Thus, by the very fact that I now say:

(1) I spoke to a man who was dead and alive at the same time.

I have created a virtual yet impossible entity *e* such that *e* is a man, is dead, and is alive, all at the same time.

Extensionalism has reigned supreme during the whole of the 20th century. The key figures are Bertrand Russell (1872–1970) and Willard V. O. Quine (1908–2000). Russell (1903: 450) shows him still an intensionalist, closely following Meinong. Commenting on extensionalism, Russell says:

> The theory seems, in fact, to have arisen from neglect of the distinction between existence and being. Yet this distinction is essential, if we are ever to deny the existence of anything. For what does not exist must be something, or it would be meaningless to deny its existence; and hence we need the concept of being, as that which belongs even to the non-existent.

But in Russell (1905: 482–483) he has switched sides and has become an ardent extensionalist, which he will remain during the rest of his life. Commenting on Meinong's ontology, he says:

> [Meinong's] theory regards any grammatically correct denoting phrase as standing for an *object*. Thus, "the present King of France," "the round square," etc., are supposed to be genuine objects. It is admitted that such objects do not *subsist*, but nevertheless they are supposed to be objects. This is in itself a difficult view; but the chief objection is that such objects, admittedly, are apt to infringe the law of contradiction. It is contended, for example, that the existent present King of France exists, and also does not exist; that the round square is round, and also not round; etc. But this is intolerable; and if any theory can be found to avoid this result, it is surely to be preferred.

Many commentators have observed that in this passage Russell does not do justice to Meinong's views. His objection, moreover, to the effect that Meinong violates the first principle of ontology and logic – the Aristotelian principle of contradiction – does not hold water because Meinong never said or implied that, for example, the golden mountain is really made of gold, only that the property of being made of gold is mentally assigned to it so that the virtual object 'the golden mountain' has the property of being made of gold in the virtual world it is part of.

A different criticism was voiced by Quine (1953) in his essay 'On what there is.' Here Quine accuses Meinong and similar philosophers of multiplying

entities beyond any controllable limits, and thus polluting any sound ontology (Quine, 1953: 4):

> Take, for instance, the possible fat man in that doorway; and, again, the possible bald man in that doorway. Are they the same possible man, or two possible men? How do we decide? How many possible men are there in that doorway? Are there more possible thin ones than fat ones? How many of them are alike? Or would their being alike make them one? Are no two possible things alike? Is this the same as saying that it is impossible for two things to be alike? Or, finally, is the concept of identity simply inapplicable to unactualized possibles? But what sense can be found in talking of entities which cannot meaningfully be said to be identical with themselves and distinct from one another? These elements are well-nigh incorrigible.

Yet, despite the wide acclaim this argument has had since 1953, it is based on the fallacy of using criteria of extensional entities and applying them to virtual entities.

The intensionalists' defense consists in saying that sentences such as those in (2) are clearly true.

(2a) The god Apollo was worshipped in the island of Delos.
(2b) Two gods were worshipped in the temple of the Dioskouroi.

In (2a), in the extensionalist view, a property is assigned to nothing because the god Apollo does not exist and therefore lacks any form of being. Russell's theory of Descriptions, presented in Russell (1905), offers no solution since the analysis it assigns to (2a) entails that Apollo exists. Therefore, to account for the fact that (2a) is true, it is necessary to assume that there somehow 'is' an entity 'Apollo.' This entity must have some identity because sentence (3) is false, despite the fact that Poseidon is as nonexistent as Apollo:

(3) The god Poseidon was worshipped in the island of Delos.

Similarly for (2b), which, in terms of modern predicate calculus should entail that there are two really existing gods who were worshipped in the temple mentioned. It seems that modern predicate calculus can be saved for natural language only if it is assumed that the existential quantifier does not require actual existence for truth but only 'being.'

Richard Montague (1972: 221–242) thought of a remedy in terms of possible world semantics. His *program of extensionalization of intensions* saw virtual entities such as Apollo as real in a class of possible worlds not containing the actual world and allowed certain predicates, such as *worship*, to yield truth with regard to entities that have reality in a class of possible worlds, even if this class does not contain the actual world. This program, however, foundered on the *problem of propositional attitude sentences*, which stands out most clearly when we consider the embedding under an intensional operator of necessarily true sentences, which are true in all possible worlds, or necessarily false sentences, which are true in no possible world. In Montague's analysis, all necessarily true sentences are substitutable *salva veritate* under intensional operators and so are all necessarily false sentences. But this means that, if Thomas holds the necessarily false belief that the number of prime numbers is finite, he must also hold the necessarily false belief that all bachelors are married, even if he himself – the best judge of his own beliefs – insists that he believes the former but rejects the latter. This theory thus has unacceptable consequences for natural language. This fact is now widely recognized.

Reference and quantification processes in natural language do not distinguish between existent and nonexistent entities. Likewise, truth is equally possible with regard to existent and nonexistent entities. When we assert (2a), we do not imply that Apollo really does or did exist. This is made possible by a distinction between extensional and intensional predicate positions. Predicates such as *bald* or *be made of gold* require the actual existence of the subject-term referents for literal truth, although they can be applied to fictitious characters under an intensional operator (which often remains tacit). But *be famous* or *be the talk of the town* or *have a website* can be truthfully said of existent and nonexistent entities alike. These latter predicates are intensional with regard to their subject-term position. The transitive predicate *worship*, for example, is extensional with regard to its subject term because one has to exist before one can worship anything, but it is intensional with regard to its object term because one can perfectly well worship specific nonexistent beings with a well-defined identity. By contrast, the transitive predicate *frighten* is intensional with regard to its subject term because something may frighten us even if it does not exist, but it is extensional with regard to its object term because one has to exist before one can be frightened.

An adequate semantics of natural language thus seems to require the assumption of virtual, thought-created, objects.

Visual Semiotics

Introduction

The study of visual signs and their representational functions became a major branch of semiotics after the publication of two influential books: Rudolf Arnheim's *Visual thinking* (1969) and Jonathan Berger's *Ways of seeing* (1972). Visual signs are defined, simply, as signs that are constructed with a visual signifier (form), i.e., with a signifier that can be seen, rather than heard, touched, tasted, or smelled. Visual semiotics is a growing and robust area of inquiry, which includes the study of art forms, logos in advertising, maps, diagrams, pictographs, alphabet characters, and other visual artifacts and symbols. Among the relevant works in this field are those by Barthes (1977), Sonesson (1987, 1994), Saint-Martin (1991), and Sebeok and Umiker-Sebeok (1994). A convenient classificatory framework of visual signs can be found in Santaella-Braga (1988).

Mental Imagery

The semiotic study of visual signs overlaps considerably with the study of mental imagery within psychology. An image is defined simply as a mental picture of objects, events, feelings, actions, situations, and ideas (real or otherwise). Images allow us to recall events, refer to them in various ways, and to generate hypothetical scenarios of situations or conditions that we may not even have actually experienced. Mental images are substitutes for real things, allowing people to recall, plan for, and predict things (Kosslyn, 1983, 1994). But these are not monolithic. Individuals differ widely in their abilities to construct images and use different aspects of imagery. For example, some people are better than others at moving objects around in their heads. They can visualize, say, the letter N changing into a Z when rotated to a certain point. Others have great difficulty in carrying out such imaginary rotations. People imagine faces and voices, locate imaginary places, scan game boards (like a checker board) in their minds, arrange furniture in a room, design a blueprint, and so on in similar, but significantly differentiated ways (Kosslyn, 1983, 1994).

Psychological studies have shown that images also vary along cultural lines. When asked to visualize a triangle or a cat, people living in the same culture will come up with very similar mental pictures of the two referents. These isomorphic images are known as 'cultural prototypes' (for the concept of 'prototype' in psychology, see Rosch, 1973, 1975, 1981, Rosch and Mervis, 1975, Taylor, 1995). The triangle that people living in Western culture typically imagine is an equilateral one, because it is the type of triangle that is perceived as the prototypical or basic form. It is the one that is perceived to be exemplary or representative of all triangles. Obtuse-angled, right-angled, and acute-angled triangles are perceived to be subtypes of the equilateral triangle. Similarly, the image of the cat that comes to the mind of subjects living in Western culture is that of a household cat, because it is the most typical in that culture.

Images are not generated only by visual perception. They can be elicited through other sensory and affective modalities. These modalities can be easily experienced by imagining such things as: (1) the sound of thunder, (2) the feel of wet grass, (3) the smell of fish, (4) the taste of toothpaste, (5) the sensation of being uncomfortably cold, (6) the sensation of extreme happiness. The image that comes to mind in the case of (1) has an auditory quality to it, (2) a tactile one, (3) an olfactory one, (4) a gustatory one, (5) a bodily one, (6) an emotional one. Moreover, images are not elicited solely by sensory modalities; they can be abstract, fictitious, or narrative. As an example of an abstract image, think of *love*. The image that this concept evokes is tied to some personal experience, such as the expression of a face in love. A fictitious image is something that can be made up in the imagination. An example of a fictitious image is a 'winged
